NOT the least instructive among the results obtained by radiography are those which illustrate its direct action on living tissues. A sufficient number of cases of Roentgen dermatitis have now been recorded to enable us to form a fairly clear idea of the pathology, if not the etiology, of this peculiar lesion. It is clear that in it we must recognise a form of slowly destructive, recoverable, but not very tractable, inflammation of the skin in all its layers. In most cases it appears that this is all. Sometimes, however, a deeper effect is evident. A paper published by Mr. T. C. Gilchrist in the February number of the *Bulletin* of Johns Hopkins Hospital, Baltimore, is of particular interest in this connexion. In it a case of x ray dermatitis is very fully described and illustrated by excellent radiographs. The patient in this instance was a healthy-looking man, thirty-two years of age, who in using a radiographic apparatus had frequent occasion to expose his right hand and forearm to the x rays for varying periods, latterly for four hours daily. The result was an extensive, puffy, dry inflammation of the skin accompanied by deep brown pigmentation, exfoliation of the epidermis, and considerable pain. Tactile sensation was markedly diminished, voluntary movement was either abolished or where retained was difficult and painful, there was marked thickening of the first and second phalanges, and tenderness over the metacarpals and the wrist joint. A radiograph taken of this hand showed, as compared with one of the normal left hand, thickening of the bones of the phalanges and metacarpals themselves, with some irregularity of outline suggesting strongly the progress of a slow osteal or periosteal inflammation. These bones were also less diaphanous than those of the left hand. The intervening joints likewise appeared to be occupied by a relatively denser medium, evidently due to thickening of their bone-surfaces. Mr. Gilchrist, in discussing the probable causation of these phenomena, attributes considerable importance to the influence of idiosyncrasy, and suggests that the active irritant itself consists of metallic particles (platinum in this case) conveyed by the kathode rays piercing the bulb of the apparatus and impinging on the vital tissues. It is to be noted, however, that no platinum was found in pieces of epidermis taken from this patient and subjected to chemical analysis. It is difficult, moreover, to admit the penetrative power claimed by this theory for metallic particles and to reconcile it with the fact that x ray dermatitis has been produced even in skin protected by clothing. None of the various explanations put forward as accounting for the changes in the skin can, so far, be accepted as entirely satisfactory. Tesla's view, that they are due to ozone generated in contact with the skin, is, as the writer of this paper says, incompatible with the changes in the bones. Professor E. Thomson[1] argues with some reason that in his own case they could not be due to electrical brush discharges, as the potential was low and no sparks were perceptible. Such an explanation seems also to be hardly compatible with the delayed onset and gradual development which commonly characterise this form of lesion of the skin. It is probable that we come nearer to the truth in ascribing this change to the action of luminous rather than caloric rays. The analogy of sunburn which has been attributed to the action of violet rays affords a suggestive parallel. As mentioned by Mr. Rushton in THE LANCET of Aug. 15th, 1896, there is ground for the assertion that luminous solar rays have a considerable power of penetration and that they are capable of producing a form of dermatitis. Mr. Hutchinson's observations in the same field of study also tend to confirm this theory. Whether light thus acts by a process of ozonisation is still open to conjecture. If it does so we seem to be in contact with another secret of nature—namely, the antiseptic property of sunlight. The whole subject doubtless calls for fuller investigation, and we must be content for a time to speak respecting it with some uncertainty, but the facts we have referred to are at least suggestive of a course which such investigation may profitably follow.

ENGLISH-MADE THERMOMETERS.

IN these days of pessimism as to the future of British industries a letter published in the *Times* of Tuesday last on the manufacture of accurate thermometers, and the facts contained therein, will be welcome reading to not a few. In the letter referred to Mr. J. J. Hicks expresses surprise at the statement of Professor Rücker (who acted as spokesman of a deputation to Lord Salisbury to urge the need and importance of establishing a national physical laboratory in this country) that no high-class mercurial thermometers are now made in England and that they are made in Germany. We were under the impression that the very reverse was the case, and that reliably graduated instruments could be obtained only from an English maker. It is a fact worth noting, also, that a very great number of thermometers are sent to Kew to be verified, and that in a great many cases they are certified after very careful testing to be without a single error, while in the case of errors the average deviation is never more than one degree. It is satisfactory, moreover, to learn that in English glass tubes we have the best possible that can be obtained, so that, to quote one instance, a capillary tube fifty-four inches long may be obtained without the slightest variation in its tiny calibre. English glass is said also to be clearer in the bore, while Jena glass is more liable to

[1] Vide THE LANCET, Jan. 16th, 1897, p. 195.

Hosted by Google

error due to contraction than English flint glass. It is quite true that if these statements, which an authority like Mr. Hicks very properly traverses, were correct some weight would be given to the argument for the establishment of a national physical laboratory in this country. Doubtless, however, Germany can produce a cheaper article, but is not that largely attributable to our apathy in nationalising scientific research and pursuits? And this, to our thinking, is a much more forcible argument.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

A WEEK'S residence in the country or at the seaside involves an outlay beyond the means of a considerable proportion of London working women, although it is unquestionable that hardly any section of the community is more in need of this kind of relaxation. A large field is therefore open to any philanthropic organisation willing to render assistance in enabling these poor people to benefit, even for a few days, by the wholesome influence of rural surroundings. The Factory Girls' Country Holiday Fund, which has now completed the ninth year of its existence and which during 1896 sent 1050 girls and women to the country or the seaside for an aggregate period of 1730 weeks, has undertaken a good work and thoroughly deserves support. The secretary is Miss Canney, St. Peter's Rectory, Saffron-hill, E.C. The income for the year was £1211 and the expenditure £1014.

THE BATHS OF LUCCA.

MR. HERBERT DANVERS sends us an account of the Baths of Lucca, which he says are much neglected. The thermal baths, which are within fifteen miles of Lucca, have been renowned from very early times, and their praise dates back to the year 983 A.D. There are two good hotels and a casino with a reading-room, and other attractions, and the springs are five in number, the temperature ranging from 98°F. to 129°F., and in constitution very much resembling those of Bath. They are fitted with every modern appliance for the treatment of disease by douches, electricity, &c., and vapour baths have been erected upon the system in use at Bath. The waters are strongly recommended in cases of renal calculus, gouty and rheumatic affections, and certain forms of skin diseases. Living is cheap, the leading hotel only charging from six to eight lire per diem for pension, and the climate and scenery are charming. The season is from May to September, and at present there is no railway within nine miles, but it is expected that by August the proposed extension will be completed. We only hope that this "development" will not, as is too often the case, spoil the place by converting it into a haunt of trippers and the *nouveaux riches* of all countries.

THE JENNER NATIONAL MEMORIAL.

THE meeting to be held on Wednesday next in the theatre of the London University, and presided over by the Duke of Westminster, ought to be one of considerable interest. The medical aspect and bearing of Jenner's momentous work will be powerfully expounded by such speakers as Lord Lister and Professor Michael Foster. And the public and State aspects of it will be dealt with by speakers of eminent authority in matters affecting public law and public health. Lord Herschell, the chairman of the recent Royal Commission on the Vaccination Acts, Sir Alfred Lyall, and Lord Playfair will speak to these points. The movement is a little belated. Not only is it a year beyond the centenary of Jenner's discovery, but it will have to encounter the competition of many forms of commemoration of the Queen's sixtieth year as a reigning Sovereign. But, even so, under the auspices of so enlightened and public-spirited a chairman and with such advocates, it is not yet too late to put the country right in regard to one of the greatest life-savers of the world. The following resolutions will be moved: (1) That the present is an appropriate time to inaugurate a work of national utility in honour of Edward Jenner; and (2) That a subscription be set on foot with the view of promoting, in connexion with the British Institute of Preventive Medicine, but in a manner distinguished by Jenner's name, researches on the lines which he initiated.

A RECURRENCE OF INFLUENZA.

THERE seems no doubt that influenza is amongst us again. Typical febriculous attacks, mostly of short duration and affecting more than one member of a family, are the indications. Generally there is some catarrh—nasal, pharyngeal, or bronchial—with more or less of the unpleasant pains of the disease. But often there is nothing but a quick sharp pyrexia occurring without rhyme or reason and leaving a weakness of the patient disproportionate to the duration of the acute stage. It is gratifying to know that the graver forms and sequelæ of the disease, as seen in former epidemics, do not often occur.

LIFE AND DEATH IN WEST LONDON.

A STRIKING comment on Mr. Sherwell's recently published book is supplied by the report of the medical officer of health for Kensington dealing with the four weeks Jan. 31st to Feb. 27th. The death-rate for the whole district is 15·9 per 1000; that for the North-West district 28·4 per 1000; and for the "special area" it reached the alarming figures of 56·2 per 1000. The causes of death in this area were mainly diseases of the respiratory organs. Kensington as a whole is admirably worked as regards its sanitary organisation; therefore, we suppose that some legal difficulties stand in the way of improving matters in this special area. The vestry are most energetic and by no means extravagant, for though the rates are high this is mainly owing to the enormous expenditure by the School Board and the County Council, as any ratepayer may see for himself by the statements on the demand notes.

THE HEALTH OF THE ARMY IN INDIA.

THE facts connected with the condition of our British Army in India presented in the vigorous and masterly report of the Departmental Committee of the House of Commons have, as may well be imagined, created a good deal of sensation. It is understood that next week Mr. Balfour will make a statement on the subject with regard to the steps which the Government intends to take, and there will be a meeting beforehand of the Service members of the House of Commons. Meanwhile, it is announced that there is to be a conference of the Liberal members to consider the action they will adopt in regard to the report. Although several Liberal members are believed to have been seriously impressed with the history of the facts that have been set forth in the papers presented to Parliament, it is understood that the Liberals intend to oppose the recommendations of the Army Sanitary Commission, taking thei stand upon the fact that the amount of venereal disease among the troops in the United Kingdom has been less, instead of greater, than it was when the Contagious Diseases Acts were in force in this country. But, even assuming—for the sake of argument—this to be the case, it is irrelevant to the question at issue, which is the increased and excessive amount of venereal disease among the European troops in India and the best way of dealing with it. That is the point, and not the state of the army at home in this respect, with which this country and the Government

Hosted by Google

are concerned. It is needless to say that this is no party question, but one for the serious consideration of men of all parties, and we have reason to hope and believe that it will be approached in that spirit.

THE HEALTH OF LORD SALISBURY.

WITH reference to the recent indisposition of the Premier we are able to state that on Friday, March 19th, Lord Salisbury was taken ill after dinner with aching all over and a feeling of *malaise*. On Saturday there was moderate pyrexia, with loss of appetite and intestinal irritation. On Sunday the symptoms abated, and on Monday the temperature had become normal and he was able to be up and dressed. His lordship has previously suffered from influenza, and his recent attack was probably a slight recurrence of the disease.

THE "DEVELOPMENT" OF TRAFFORD PARK.

As will be seen from the letter of our Manchester correspondent in THE LANCET of March 20th (p. 843), Trafford Park is to be "developed." This is the modern euphemism for "spoiled." The estate consists of about 1200 acres with a magnificent old house, and the latter is to be converted into a hotel. The developments include the proposed erection of such health-giving objects of beauty as flour mills, oil tanks, seed-crushing mills, and works for the distillation of tar, also wharves and railways. Surely it is not too late for something to be done to prevent such an outrage, for an open space such as this is of absolutely incalculable value to the dwellers in the neighbourhood. It seems to us that a portion of the funds being collected for various objects in celebration of Her Majesty's reign might well be devoted to buying out the present owner or owners and setting this magnificent "lung" free to do its beneficent work for the benefit of both the present generation and those yet unborn.

THE REGISTRATION OF MIDWIVES.

A MEETING was recently held at London House in support of the Midwives Registration Bill. Mrs. Creighton presided, and is reported as saying that "what surprised her most was that there should be the least need for such a meeting." She then went on to explain the objects of the Bill, saying that what they wished to prevent was that a person should deceive the public by assuming a position she was not entitled to occupy. Dr. Champneys spoke of the necessity of some measure for the registration and supervision of midwives, and a resolution pledging the meeting to support the Bill now before Parliament was carried. We must say that Mrs. Creighton's naïve confession of ignorance as to why there is opposition to the Bill somewhat surprised us, for surely it is incumbent upon the supporter of a measure to make himself or herself acquainted with the point of view of the opposition. As we have many times previously said, training and supervision are necessities, but we do not think the present Bill is the best way to procure them.

A GOOD IDEA.

ACCORDING to a special correspondent of the daily press the English and American residents in Antwerp, backed, we are glad to say, by a section of the Belgian inhabitants, have been agitating for some time to get an abattoir for horses erected close to the docks, and, what is still more gratifying, the authorities have nearly decided to build one. This will not only spare the feelings of the inhabitants, now daily outraged by the mournful procession of wretched, broken-down horses to the present slaughter-house, but will also render the last moments of these poor animals' lives a little less miserable. They are generally in the worst possible condition, and the long, weary tramp to the abattoir after having undergone the sufferings of a sea voyage is by no means the least of the miseries they have to encounter. In our opinion we are by no means blameless on this side of the North Sea. We do not in the least object to people eating horseflesh, if they like it, and provided they do not get it when they ask for beef or mutton; but we do think that the export trade in live worn-out horses should be stopped. We make a virtuous protest about the treatment of horses in a Spanish bull ring, and it must be owned that it is not a pleasant spectacle, but any way there the agony is by comparison but short. If anyone is permitted to sell horseflesh to foreigners to eat, and it is supplied from this country, it should be killed upon this side.

THE METROPOLITAN ASYLUMS BOARD AND PAUPER CHILDREN.

THE Metropolitan Asylums Board has intimated its willingness to undertake the administration of the new order of the Local Government Board for the benefit of Poor-law children suffering from ophthalmia, diseases of the skin and scalp, defective intellectually or physically, ordered by justices to industrial schools, or otherwise requiring special treatment as convalescents. The Metropolitan Asylums Board accepts this extension of its duties professedly in the interest of economy. We are not aware that the Board has shown any special faculty of economy in its past history, but perhaps it may be so impressed with the costliness of its own past work as to avoid errors into which an inexperienced and brand-new body might fall. One effect of this new departure wil be to give a clearer Poor-law character to the work of the Metropolitan Asylums Board. We do not altogether object to this aspect of the new arrangement. Whatever the legal definition of pauperism, the practical conception of it must be the resort to institutions supported by rates and taxes, and such resort should be restricted to those who have no reasonable alternative. We do not doubt that under the Metropolitan Asylums Board the cases of disease will be much better cared for than at present. But that such huge groups of diseases should acquire such incurable intensity under the care of the guardians is a condemnation, concurring with others, of their failure from a medical and sanitary point of view.

THE NEW REGISTERS.

WE have received copies of the Medical Register for 1897, and the Dentists' Register for the same year. It is evident that—despite the cry about the overcrowding of the profession and the consequent lack of employment to be found, remunerative employment that is—there is no appearance of any falling off in the number of candidates for admission to the ranks of the profession. Thus in 1896, besides the 52 names restored to the register, there were 1385 new registrations. The removals from death and other causes numbered 560, making a total increase of 877 names, so that the number of practitioners in the United Kingdom is now 34,478 as against 33,601 in the previous year. We fancy, however, that the number of names removed by death is understated, and could point out more than one instance of a name being retained after death. With regard to the Dentists' Register, the number of names is less than it was in 1896 by seventy-five, and the total number on the register is now 4860, as against 4935 for last year. This diminution is accounted for by the fact that only those persons holding the qualification of Licentiate in Dental Surgery can be added to the register, while the erasures affect not only licentiates but all that large class who were in "practice" before 1878. The percentage of Licentiates in Dental Surgery to the whole number on the register is constantly

Hosted by Google

increasing, being now 31·25, as compared with 28·88 in 1896 and 9·13 in the year the Dentists' Register was first published—namely, 1879.

THE following appointments have been made by H.R.H. the Duke of York: Mr. Frederick Treves, F.R.C.S. Eng., to be Surgeon-in-Ordinary to His Royal Highness; and Dr. Alan Reeve Manby to be Surgeon-Apothecary to His Royal Highness at Sandringham.

THE portrait of Lord Lister, P.R.S., by Mr. W. W. Ouless, R.A., is now finished. The presentation will take place in the lecture theatre of the Royal College of Surgeons of England, Lincoln's-inn-Fields, at 5 P.M. on Monday, March 29th.

MR. GILL, a foundationer of Epsom College, has been elected to a mathematical scholarship at Magdalene College, Cambridge.

THE Bill for the Registration of Midwives was set down for second reading on Thursday night.

The Lancet Special Commission
ON THE
METROPOLITAN WATER-SUPPLY.

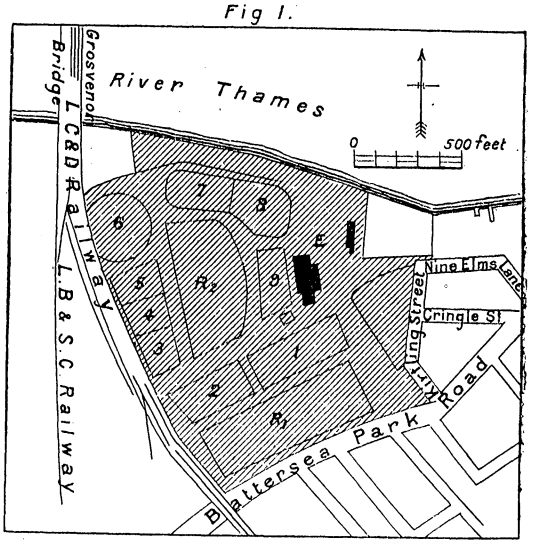
VI.[1]

THE SOUTHWARK AND VAUXHALL WATERWORKS COMPANY—*continued.*

Pumping arrangements.—The work to be done is: (1) raising water derived from the natural filtration system and from the river to filters 8 and 9; (2) pumping unfiltered water to Battersea; and (3) pumping filtered water to Nunhead and to the districts supplied. The water is raised to the filter beds by a pair of inverted compound-geared engines and a set of tri-compound-geared engines. The head of water worked against is 16 ft. Three inverted direct-acting Cornish engines of the Bull type are used for pumping to Battersea. The head of water worked against is 135 ft. Two single-acting beam engines with double-acting pumps and two pairs of direct-acting compound inverted rotative engines are used for pumping to Nunhead.

Distribution of the water from Hampton.—From Hampton the water is distributed in two different directions.

The filtered water passes in a 42-in. main in an easterly direction along the high road which passes just to the north of Hampton Court Palace to Hampton Wick. At this point the main goes in a tunnel under the Thames to Kingston. The tunnel under the Thames is in the London clay. It can be inspected from either end, and ladders pass down to the bottom of the tunnel. The tunnel itself is kept dry by a small water-pressure engine worked by the pressure in the main. From Kingston the main passes in a direction nearly due west close to Coombe House and by Raynes Park to Merton and Streatham, then in a north-westerly direction to the north of Lower Norwood and Dulwich College to Nunhead.



The unfiltered water passes from Hampton in a 36-in. main. There is another main, 30 in. in diameter, which conveys filtered water from Hampton for the supply of the western portion of the Company's district. This is laid parallel with the 36-in. main just mentioned. The two mains pass in a north-easterly direction to Twickenham, then under the Thames just below Richmond Bridge, and then in an easterly direction to Wandsworth. From Wandsworth the 30-in. main passes through Clapham, Kennington, and Camberwell to the service reservoirs at Nunhead. The 36-in. main from Wandsworth takes a more northerly course and conveys the water to Battersea, where it is filtered.

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Feb. 20th, 27th, and March 6th, 13th, and 20th, 1897, respectively.

Wandsworth.—The station at Wandsworth is situated on the banks of the Thames and of the Wandle where that stream joins the river. The water is brought from Hampton in the 30-in. main just described, and reaches Wandsworth at a pressure of about 100 ft. At Wandsworth the pressure is raised to 200 ft. or 220 ft., and the water goes to supply the higher parts of Wimbledon and the high service reservoir at Nunhead. The water is pumped by two direct-acting, inverted, quadruple expansion, rotative engines, for which the steam is generated by four Badcock and Wilcox tubular boilers, which are usually worked at a pressure of 120 lb. The engine house is built of white bricks with terra-cotta facings, and the inside is lined with shiny, white tiles and is very well lighted. There is at this station an engineer's work room, a blacksmith's shop, and a good lodge.

Battersea.—The water is delivered from Hampton by a 36-in. main and passes into three reservoirs, which have an area of twelve acres and are capable of containing 46,000,000 gallons of water (Fig. 1, R_1, R_2.) From the

Fig 1.

Battersea Station. R_1, R_2, Reservoirs. 1 to 9, Filter beds. E, Engine house and stand-pipe.

reservoir the top-water passes through pipes which are chained to floating buoys, into the filters (Fig. 1, 1 to 9), which have an area of eleven and a quarter acres. From Battersea the water to the district is supplied by one 27-in., one 24-in., three 15-in., and one 12-in. mains. These are not all shown in the map. For the supply of the high-level districts the head of water worked against is 330 ft. and the water is pumped by two beam engines, which have cylinders of 55 in. and work pumps of which the diameters are 15⅝ in. and 15 in. respectively and have a stroke length of 8 ft. Three other engines which supply the district work against a head of 170 ft., the water (or some of it) passing through a stand-pipe 170 ft. in height. The description of these engines may be summarised thus:—

—	Diameter of cylinder.	Diameter of pump.	Length of stroke.
No. 3	68 in.	33 in.	10 ft., 0 in.
No. 4	64 in.	33 in.	9 ft., 6 in.
No. 5	112 in.	50 in.	16 ft., 0 in.

The engine No. 5 is said to be the largest of this type in England and to be capable of raising 12,000,000 gallons of water daily, working against a head of 170 ft. There is also a direct acting engine of the Bull type capable of lifting 5,200,000 gallons of water, working against the same pressure. The Battersea station contains carpenters' and blacksmiths' shops, cottages, and a large yard which contains stores of pipes. The sanitary arrangements here are not strictly in accord with modern ideas. The station will not be used after the completion of the alterations which are now in progress at Hampton.

Hosted by Google

Streatham.—The station is situated in a field not far from Streatham-common railway station on the London, Brighton, and South Coast Railway. The top of the well is 110 ft. above ordnance datum. The depth of the well shaft is 148 ft., and below this it is lined with cylinders to a depth of 242 ft. The water level is about 45 ft. from the surface. A careful record was made of the strata cut through. The results are given below.

Grey, micaceous sandstone, here and there with reddish bands					
About 1255 ft. with fish remains (?) ...					
Grey and red rock as above; a few inches	8	0	.....	1258	0
Light-grey, coarse, very micaceous sandstone, with black carbonaceous patches; about 20 in.					

The boring was continued to the depth of 1271 ft.; but the last 13 ft. of core were not brought up. The amount of water which it is estimated can be obtained from the well daily is 2,000,000 gallons. The water is bright and clear and has a slightly ferruginous taste. It is pumped by two double-acting lift pumps driven by two sets of triple-expansion engines, and the steam is generated by three Badcock and Wilcox boilers. In a building adjoining the engine and pump houses there is an arrangement for filtering the well water through calico, but this operation is not considered to be necessary by the Company.

Forest Hill.—This station is situated on the summit of Forest Hill, 345 ft. above ordnance datum. The reservoir is built with arches, completely covered in and turfed at the top. It is capable of storing 1,000,000 gallons of water. The reservoir was empty when visited on Dec. 10th. The residence of the assistant-engineer and a cottage for a caretaker are situated here.

Nunhead.—The station at Nunhead (see Fig. 2) contains

Fig 2.

Nunhead Station, Peckham. 1 and 2, High-service reservoirs. 3 and 4, Low-service reservoirs. E, E, Engine house and offices.

reservoirs, pumping arrangements, an office, a valve house, workshops, and the residence of the engineer. The high-service reservoirs (Fig. 2, 1 and 2) are situated at the top of the hill 200 feet above ordnance datum, and they are capable of storing 6,000,000 gallons of water. The low-service reservoirs (Fig. 2, 3 and 4) are situated on the slope of the hill 168 feet above ordnance datum, and have a capacity of 12,000,000 gallons. The reservoirs are arched over and covered with turf. The engine house contains two Bull engines, which are worked by four Cornish boilers. The engines are used to pump the water to the high-service reservoirs. A fire-engine is kept at this station. It is occasionally used to empty service pipes rapidly when a pipe has burst. In such a case the fire-engine is at once despatched to the place at which the accident has happened. The brasswork here, it may be noted, is kept in a way which would be no discredit to a smart man-of-war, and the engine house, like all the newer ones put up by the Company, is extremely well lighted and airy. The valve house, which is situated near the entrance gate, contains the arrangements for regulating the direction of the water-supply; the distributing mains all pass through the house. The office is in telephonic communication with the district inspectors, with the office in Southwark Bridge-road, Streatham, Wandsworth, Forest Hill, and the Metropolitan Fire Brigade at New Cross and at Kennington, and there is a private telegraph wire to Battersea and to Hampton.

Communications with other companies' mains.—There are two communications with other companies' unfiltered water mains: (1) with the Grand Junction Company at Hampton—a 15-in. connexion; and (2) with the West Middlesex Company at Marsh-gate near Richmond—a 36-in. connexion.

Length of new pipes.—The length of new pipes ranging from 3 in. to 20 in. laid in 1895 was ten miles, and during the year 1896 six miles.

Hydrants.—The number of hydrants erected during the year 1895 was 3829, and during the year 1896 it was 4137.

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 106,604; on Dec. 31st, 1895, 109,670; and on Dec. 31st, 1896, 112,455.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 93·75.

Average daily supply per head.—The average daily supply per head for the year 1896 was 38·39. These figures are arrived at by the Company as follows. The number of supplies afforded is 119,948, and these figures are multiplied by 7·43, which is supposed to be the average population per house in the district supplied.

Dates of maximum and minimum supply.—The following table gives the date of the maximum and minimum supplies and the average daily quantities supplied.

	Year 1895.		Year 1896.	
—	Month.	Quantity in gallons.	Month.	Quantity in gallons.
Maximum ...	September	39,148,588	July	37,591,943
Minimum ...	February	26,630,684	November	31,657,101

Table of Statistical Details given by the Southwark and Vauxhall Waterworks Company for the year 1896.

SUPPLY.	Average daily supply in gallons	31,996,895
	Percentage delivered for other than domestic purposes, exclusive of waste	15 to 20
	Number of houses supplied	119,948

Area of Supply.

The Act of 1852 authorises the Southwark and Vauxhall Company to supply the following places, some of which are entirely supplied, some partly supplied, some not supplied:—

Supplied: St. Thomas, Southwark; St. John, Southwark; and St. Olave, Southwark.

Partly supplied: Battersea, Bermondsey, Brixton (Lambeth), Camberwell, Clapham, Christchurch (Surrey), Deptford (St. Paul), Dulwich, Kennington, Lambeth, Peckham and Peckham Rye, Newington (St. Mary), Rotherhithe (St. Mary), St. George the Martyr (Southwark), St. Saviour (Southwark), Stockwell, Walworth, and Wandsworth.

Not supplied: Deptford (St. Nicholas), and Streatham (St. Leonards).

The Act of 1884 authorises the Company to supply the following places, all of which are entirely supplied with the exception of one place which is partly supplied:—

Supplied: Barnes, East Sheen, Ham, Kew, Mortlake, Petersham, Roehampton, Sheen, and Wimbledon (parts above the 100 ft. ordnance contour line).

Partly supplied: Putney.

The Company also supplies water by bulk to the Corporation of Richmond.

New Works in Progress.

Hampton.—In the description of the present state of the Company's station at Hampton it was said that work was in active progress there and a plan was given showing the site of the operations (see THE LANCET, March 20th, 1897, p. 828, Fig. 1). The works are as follows: (1) two storage reservoirs, which will have a total capacity of 300,000,000 gallons; (2) a subsiding reservoir, which will have a capacity of 40,000,000 gallons; (3) seven new filters, which will have a total area of seven acres; and (4) a new engine and boiler house, which is to be supplied with engines of 1500 indicated horse power.

Merton Abbey.—A new well is being dug at Merton Abbey. The shaft is 12 ft. in diameter and the depth now reached is about 90 ft.

Raynes Park.—Boring operations are in progress at Raynes Park and the chalk has been reached.

It is proposed also to construct at Honor Oak a covered service reservoir capable of holding 60,000,000 gallons.

HISTORICAL NOTES ON MEDICINE, SURGERY, AND QUACKERY.

II.[1]

FOR a century and a half Liverpool can boast some "original" medical men, and in the present article it is proposed to give an account of some of them. In St. Nicholas's Churchyard there is or was to be seen near the gate at the middle of the south side an inscription to the memory of a medical practitioner of the seventeenth century: "Here lyeth the body of Alexander Norres of Leverpoole, professor of physick and chirurgery, who departed this life the 5th day of July, was buried the 8th, 1700." For the credit of "physick and chirurgery" it is to be hoped that this was not the Alexander Norris who was Mayor of Liverpool in 1694, and who had to beg pardon on his knees in the House of Commons for his misconduct in returning as M.P. one Mr. Thomas Brereton, who had but fifteen votes, instead of Mr. Jasper Mawdit, the recipient of 400 votes. His worship was discharged on paying fees, after being imprisoned for about seven weeks.

Two hundred years ago, when the burials in Liverpool were only 158, a popular medical man was Dr. Silvester Richmond, who, in 1692, gave £100 to erect almshouses on Shaw's-brow, the site of St. George's Hall. After his death his widow repaired them. By the way, in later days, when Liverpool was famous for its pottery, the bottom of Shaw's-brow, facing the Haymarket, was called St. John's Village. Up the south side of Shaw's-brow were the potters' dwellings. It is said that in the time of the resurrectionists these men were in the habit of handling "clay" of a sort not required in their daily work, and that they got over the churchyard wall and exhumed any newly interred bodies, taking them into their houses, and selling them to the medical students and others who purchased such "subjects." This Dr. Silvester Richmond incurred the displeasure of James II., for, at a Court held at Windsor on Aug. 14th, 1687, His Majesty, having received information of the "misbehaviour" of Oliver Lyme, deputy-mayor of Liverpool, and Silvester Richmond, a justice of the peace there, thought fit to order their removal from their offices in the town of Liverpool. Their "misbehaviour" was their opposition to the King's schemes, and both of them were restored to office after the Revolution. Dr. Silvester Richmond was a member of an old Liverpool family. He filled the civic chair in 1672, and his descendants have been connected with the town down to a recent period. On a brass-plate screwed to a seat in the chancel of St. Nicholas's Church is the following inscription: "Here lieth the body of Silvester Richmond, Professor of Physick and Chirurgery, who after near thirty years indefatigable care and successful practice in this town and country, at last exhausted that life which had been so carefully employed in the preservation of many others. He died the 16th and was interred the 19th April, 1692."

In the Norris Papers, published by the Chetham Society, it is stated that the surgeon received £8 12*s.* for "seering the body" of Mr. Thos. Norris, former Mayor and Member for Liverpool, and Sheriff of Lancashire, who died at Harrogate in June, 1700. At the time of his death two of his brothers were absent in India. One, Sir William Norris of Speke, had been selected by "The English Company trading to the East Indies" as its Ambassador to the Court of Aurungzebe, "the Great Mogul." The other brother, Edward, practising as a physician at Chester, was selected as secretary to the Ambassador. Edward Norris was of Brazennose; M.A., June 1st, 1689; B.M., Jan. 19th, 1691; and M.D., March 12th, 1695. In the procession of April 28th, 1701, with which the Ambassador entered the Mogul camp at Parnella, we find: "Edward Norris, Esq., Secretary to the Embassy, in a rich palanquin, bearing His Majesty's letters to the Emperor; on each side, Mr. Wingate and Mr. Shuttleworth, in rich laced coats, on horseback." The sword of state which was borne before the Ambassador in this splendid procession is now deposited amongst the regalia at the Liverpool town hall. Dr. Norris sailed, with fourteen of his brother's suite, in the *China Merchant*, a vessel bearing a rich cargo, of which 60,000 rupees in value belonged to the Company and 87,000 to Sir William Norris. The brothers again met at the Mauritius and sailed with a large fleet for England; but the *Scipio*, the Ambassador's vessel, parted company, and Dr. Norris saw his brother no more, Sir William Norris dying at sea. Although Dr. Norris returned to England, yet the calm which succeeded to perils and anxieties operated fearfully on his mind. On July 18th, 1703, his sister, Mrs. Hopwood, wrote as follows: "But the concern I am in for my poor dear mother on the account of my dear brother hath filled me with such apprehensions it is as much as I can do to bear up, though had it not been for that paper mother showed me after the unlucky thing of the banqueting house I should never have suspected anything of that kind; I hope it will wear quite off; his friends must not let him be too much alone, tho' I am in constant fear for him, God will be so merciful to him as perfectly to restore him."[2] Dr. Norris was perfectly restored. On his return the Speke estate was to the extent of two-thirds of its value pledged to the annuities of his mother and sister-in-law and the other third nearly taken up by debts. He resided for a while at Utkington, near Chester, and in 1705 married the daughter of William Cleiveland of Liverpool. This lady is marked in the pedigree as his second wife (we discover no mention of the first in the Norris Papers), and after his death she is stated to have married Dr. Tarleton. The death of this doctor's first wife took place Oct. 15th, 1702, and he married again a Mrs. Norris in the lifetime of Dr. Norris. The inscription on Dr. Norris's tomb in Garston Chapel goes far to convict the Norris pedigree (to which the name of that excellent herald Lodge is, we suspect, very improperly appended) of this mistake: "Under this tomb lies interred Edward Norris, M.D., of Speek, who departed this life the 22nd of July 1726, in the —— year of his age. Also Ann, his wife, died the 3 of Jany., 1729, aged 53." They had one son, born in 1712, who it may be conjectured survived his father, yet was dead before 1736, and with him the name of Norris of Speke ceased to exist. Mary Norris, the niece, became the heiress of the whole Speke property, and being

[1] No. . was published in THE LANCET of March 6th, 1897.

[2] Mr. Thos. Heywood, F.S.A.: Introduction to the Norris Papers.

Hosted by Google

thirty-six years old married the worthless Sidney Beauclerc, fifth son of the first Duke of St. Albans, "a man of bad character." Dr. Edward Norris was returned for Liverpool to the Parliament of 1714, elected on the accession of George I., and continued to represent the town until 1722. Dr. Norris's granddaughter became the wife of Mr. Richard Pennant, M.P., of Penrhyn, near Bangor, who was afterwards created an Irish peer under the title of Baron Penrhyn. Lady Penrhyn was well known in Liverpool as an active electioneering agent, and died June 1st, 1816.

In the "Records of the Mock Corporation of Sephton" is the following entry: "Mr. Andrew Fillan (an ancient burgess), on the motion of Burgess Cobham, seconded by the Recorder, was unanimously admitted physician to the corporation, on which occasion he took the oath of office in such a manner as convinced the company present that he was fonder of the contents of the mace than any draught in the whole Materia Medica." Drinking on the mace was one of the customs connected with the admission of members. The aspiring candidate had to take "the oath" and then drain the mace, if possible, at a breath, at a wind, or at one "tip"—i.e., of the mace—as the records express it. Nearly every member of the "corporation" bore some whimsical title, often borrowed from the business or profession to which he belonged. Sometimes it was far from flattering. Out of more than 300 members constituting this Mock Corporation nearly 200 appear in Gore's Directory of 1791 as Liverpool gentlemen, merchants, and tradesmen. In 1787 a Mr. Zuill was sworn in physician to the corporation, and Mr. Moss of Liverpool, surgeon, having "refused the Honor of becoming a Member, and therefore he is deem'd disqualified from ever being a Member." Mr. Beckett was "druggist to the Corporation and apothecary, &c.," in 1788. On Sunday, Jan. 25th, 1789, Mr. James Brown of Liverpool, surgeon, dined with the "corporation" as a visitor. After dinner "the Recorder begged leave to recommend Mr. James Brown as a fit and proper person to be admitted to the Franchise of Burgess of this antient and Loyal Corporation, and the motion being Seconded by the Worshipful the Mayor, it was carried unanimously in the affirmative. Mr. Brown was accordingly admitted, took the usual oath, and drank his ale like a man." This was very different to the conduct of a Mr. Bevan, elected rather unwillingly to the position of "Groom of the Stole to the Corporation," who was "sworn in and drank his oath in ale, which he, however, did not do with such *gout* as it was at first imagined so honourable a Burgess recommended to so honourable a Dignity would have done; for Oh, strange to tell! he made Three pauses at Swigging one pitiful pint of ale."

At Bootle on Sunday, March 15th, 1789, several members of the corporation dined together, and were afterwards visited by Henry Stanistreet, M.D., and other gentlemen. Dr. Stanistreet and a Mr. James Bevan of Ashton were admitted "to the Franchise of Free Burgess, took the usual oath, and drunk their Liquor like men. N.B.—The former smiled and made 2 bites of a cherry; the Latter drank his ale gallantly indeed." Mr. James Bevan was proposed by Burgess Taylor, and seconded by the Mayor, to the office of Rough Rider to the corporation. This was carried *nem. con.* Dr. Stanistreet was proposed by Burgess George Bevan and seconded by Alderman Whaley to the office of physician; this was carried *nem. con.* In the following May Mr. John Zuill, junior, was admitted and took the usual oath, "which he drank in such stile as clearly evinced he was a chip of the Old Block." The name of Dr. Rutter also occurs among the members of the corporation. The corporation ordained "that a Common Hall be annually holden on every ffeast of Saint Luke and 1st day of April, and the reason why the Common Halls are proposed to be holden on those days are, with regard to the first, because Saint Luke was a very learned physician and well skilled in ye cure of lunatics, and with regard to the last, because on the 1st of April many Artificial Patients of that description are not infrequently exhibited." At Sefton, on Sunday, Sept. 19th, 1790, Dr. Fillan was proposed and duly admitted, taking the oath and drinking his ale "cheerfully." Among the titles of the office bearers in this very convivial corporation we find the following: Overseer of Bastard Children, Punch Maker, Brazier and Tinker General, Master of the Revels, Window Peeper, Hooper, Cooper and Powder Keg Maker, Chafe-Wax, Poet Laureate, Commissioner to the Hackney Coaches, African Committee-man, Attorney General, &c. At a Sunday meeting at Bootle it is recorded of them that "they dined like men of Gath and proved the strength of the human appetite *ad maximum*, and concluded their repast with a bottle of good old Sherry from the Vaults of Alderman Newsham, the Corporation Vintner." On Sunday, July 26th, 1789, fifteen of the members met at Sefton, where they had "excellent Westphalia ham & best London particular Madeira on the occasion in the Council Chamber." They occasionally drank port wine 130 years old. After careful examination of the printed records we find that, with the exception of the instances mentioned above, the relations of the medical men of Liverpool to the mock corporation were purely professional, or, in other words, it is highly probable that the excesses of the members made work for the medical men. Even the medical men whose names appear in the records as admitted members do not appear to have subsequently taken a conspicuous part in the meetings or been regular in their attendance. Notwithstanding their roystering and vagaries, it must be borne in mind that the members of the mock corporation were men of great influence in Liverpool.

In Union-street resided in the middle of the eighteenth century Dr. Samuel Angier, an eminent physician. He married Catherine, daughter of George Leigh of Oughtrington, and was connected with the old Liverpool family of Clayton. In a commodious house at the corner of St. Paul's-square and Virginia-street, about the year 1770, lived Dr. Henry Richmond. This physician was the father of the Rev. Legh Richmond, rector of Turvey, Bedfordshire, the distinguished author of "The Dairyman's Daughter." Dr. Richmond's father was one of the rectors of Liverpool. Mr. Matthew Turner, surgeon, of John-street, was an excellent chemist. He re-discovered the lost art of staining glass, and in conjunction with a clever artist of the name of Chubbard executed the south window of St. Anne's Church, Liverpool. Mr. Turner was also a wit, and was the cause of a good deal of merriment in advising His Majesty King George III. not to fret at the loss of his American colonies, for Herschel had made amends by discovering a world *in nubibus*, alluding, of course, to the planet Georgium Sidus. Mr. Turner was a member of the first society, formed in 1769, for the establishment of an academy of painting and sculpture in Liverpool, as was also Dr. Matthew Dobson. After a few months' trial the scheme was abandoned, but was revived in 1773. Courses of lectures were delivered, including lectures on anatomy by Mr. Turner and on chemistry by Dr. Renwick. The time, however, was unpropitious, and the society, which numbered William Roscoe among its promoters, was dissolved. Mr. Turner early in his professional career proposed the establishment of a lying-in hospital in Liverpool, as will be seen from the following advertisement, which appeared in the *Liverpool Chronicle and Marine Gazetteer* for May 6th, 1757. This was eighty-four years prior to the founding of the Institution for Married Lying-in Women in 1841, and forty years in advance of the Ladies' Charity, established in 1796.

"A lying-in hospital in this town being what many charitably disposed persons have desired and thought very necessary, and as such a design, if put into execution, must require a considerable time before it can be compleated, the following Proposal is made as an attempt to relieve the most pitiable part of the lying-in poor in the meantime.

"As many unfortunate poor women and their infants suffer greatly through the insufficiency of their Midwives in Difficult Cases; and as the expense of calling in a Man-Midwife at such times often prevents the indigent from having proper Assistance; and as there is a proper place of reception for all other sick poor already provided in town, free of charges, but none for this particular purpose, which deserves at least equal consideration; and as almost every person is engaged at this juncture in contributing, each according to his particular talent, towards relieving the distresses of the poor, —I judged my endeavours for this end might not be unacceptable; I do therefore hereby inform the public that I am ready to attend and assist to the best of my power Gratis, all such married women, living within the limits of this town, whose Cases in labour are Difficult or Dangerous, so that the midwife is at a loss, or unable alone to perform her Office, provided they are not able to pay.

"But, considering that some persons may, from the tenor of this Advertisement, insinuate that the design may not proceed from any motive of Compassion, but only for my own Improvement, to try experiments, or to practise upon the above-mentioned objects of pity, it may not be amiss to obviate these objections (as I have practised but a short time in this town) by further observing to the public that

Hosted by Google

I have studied and practised Midwifry in two of the Chief Schools for that Art in Europe; of the truth of which any person may be satisfied, by only calling at my house, where they may see it certified under the hands of Doctor Smellie, teacher of Midwifry in London, and of Mons. Levret, Censor of the Academy of Surgery, and Professor of Midwifry in Paris. "M. TURNER.

"Atherton-street, Liverpool, May 2, 1757.

"N.B.—'Tis hoped that the Gentlewomen who practise Midwifry in town will not look upon anything here mention'd as designed to prejudice or undervalue them, the design being only to give them assistance when 'tis wanted, which I judge may be offered to them in the manner here proposed, without any Impeachment of their abilities, by those who may be allowed to have had better opportunities of acquiring skill in the profession than the Practitioners of their sex usually have."

Mr. Turner may have found "the Gentlewomen who practised Midwifry in town" too many for him in this benevolent project, for I cannot trace any further record of his labour in this direction. In the guarded phraseology of his footnote he appears prophetically to anticipate the delicate relationship of the "gentlewomen" in question towards the medical profession, as unpleasantly emphasised not long ago in the case of the Liverpool Lying-in Hospital.

The year 1745 is memorable in the annals of Liverpool, not only for the attachment of the inhabitants to the House of Hanover, but for the commencement of a great public charity which still flourishes. Several addresses had been published in the town from time to time previously to the year 1745 recommending the forming of a public infirmary. These induced the clergy, physicians, surgeons, merchants, and tradesmen, with some neighbouring gentlemen, to open a subscription for erecting a new building in the year 1745 upon a field, the site of the present St. George's Hall, given by the corporation for a term of 999 years. In July the work was begun and carried on with great vigour, but owing to the rebellion of 1745 the house was not finished till the latter end of 1748. Then the two upper wards were furnished with thirty beds, "which was judged nearly equivalent to the yearly subscription for the support of that number of persons." On March 25th, 1749, the house was opened for the admission of patients. The officers for the first year were the Right Honourable Edward Earl of Derby, President; Mr. Foster Cunliffe, treasurer; Mr. Chas. Goore and Mr. Edward Deane, deputy-treasurers; Mr. Samuel Ogden and Mr. Thomas Seel, auditors; Dr. Walter Greene, Dr. John Kenyon, and Dr. Thomas Robinson, physicians; Mr. James Bromfield, Mr. Thomas Antrobus, and Mr. William Pickering, surgeons; and the Rev. Matthew Lowe, chaplain. The subscriptions to the building fund amounted to £1809 13*s.* 5*d.* in Liverpool, and to £438 13*s.* 6*d.* in the country, making a total of £2248 6*s.* 11*d.* The yearly subscription list amounted to £486 14*s.* 6*d.* The cost of building the infirmary was £2648 7*s.* 11*d.*, of which sum about £400 was borrowed. The number of in-patients admitted in 1749 was 122, and out-patients 72. In glancing over the list of subscribers to the building and founding of the infirmary, which includes the names of the principal inhabitants of Liverpool in the year 1745, it is interesting to note the amount of support rendered to the good cause by the profession itself: Alderman John Bromfield, surgeon, subscribed £32 6*s.*; George Dickins, M.D., £5 5*s.*; Richard Gerard, apothecary, £21; Edward Livesey, surgeon, £10 10*s.*; and Samuel Nicholson, M.D., £5 5*s.* These subscribers and the physicians and surgeons of the charity make in all eight gentlemen practising in Liverpool in the year of the rebellion. Yet there must have been one more, for we know that in that very year of trouble there was born in Water-street a "man child" destined to be one of Liverpool's most distinguished surgeons, and to perform in the institution then being founded a triumphant operation in conservative surgery. We mean Henry Parke, whose father also was a surgeon, but whose name does not appear in the list from which we have quoted.

In Gore's Directory for 1781 the names of the following were given as "medical gentlemen who attend gratis" at the infirmary:—Physicians: Dr. Thomas Houlston, Dr. Joseph Brandreth, and Dr. Joseph Camplin. Surgeons: Dr. John Lyon, Mr. Henry Parke, and Mr. Edward Alanson. It is interesting to note that the gardens for the use of the convalescents extended to where are now the steps leading to the esplanade in front of St. George's Hall. Mr. F. W. Lowndes, in his pamphlet on Venereal Diseases and Prostitution in Liverpool, states that the late Mr. Minshull, surgeon, remembered the old infirmary and that cases of venereal disease were treated there. The wings of the old infirmary were occupied as the Seamen's Hospitals. They were receptacles for decayed seamen and their wives. The seamen sailing from Liverpool contributed sixpence per month by Act of Parliament for their support. They were erected in 1752. The lunatic asylum and infirmary on being closed were used as barracks. The lunatic asylum stood at the corner of St. John's Cemetery, where all sorts of people were interred, those who had "gone to their death" by mischance or committed suicide or died in prison. In 1806 a huge pit was dug in the cemetery, and covered by folding doors or flags. The dead were deposited in the pit, and the earth was thrown upon each layer of coffins as it was completed. In 1816 a writer in the *Mercury* complained of the frightful stench arising from the public grave in the Parish Cemetery, and suggested that a similar contrivance to that used in St. John's-yard should be constructed to cover it. In 1804 some limekilns which stood in Lime-street on the side of the railway station, near Lord Nelson-street, were suppressed, the proprietors being indicted for a nuisance by the authorities, the physicians attending the infirmary giving evidence of the injurious effects of the azotic gas on their patients suffering from pulmonary complaints. The house at the upper corner of Newington-street and Bold-street, now converted into shops, was erected in 1788 by Henry Parke, commonly called Harry Parke, surgeon, who resided there for thirty-two years. He was descended from an old Liverpool family. His father was a surgeon residing in Water-street, where Henry was born on March 2nd, 1745. He commenced practice in 1766 in Basnett-street. This was then considered such a distance from the centre of the town that his friends remonstrated with him for going so far out of the way of his patients. In 1788 he removed to Bold-street, and in 1820 he retired to a suburban retreat at Wavertree, and died on Jan. 28th, 1831, in the eighty-sixth year of his age, full of years and honours. Mr. Parke was not the least eminent of the many distinguished men who have raised the fame of the medical and surgical school of Liverpool. During a long professional life he did much to increase the reputation of the practice of surgery in his native town. His work on the "Excision of Carious Joints" passed through several editions. The following tribute to his merits appeared in an article on Surgical Science in the *Edinburgh Review*, October, 1872: "In the latter portion of the last century, when a vigorous flash of originality seemed to light up the annals of surgery, Parke, of the Liverpool Hospital, may be said to have accomplished the first act of conservative surgery. The fact of his patient being a sailor, to whom the loss of a foot and leg would have been tantamount to the loss of his means of getting bread, determined him to make the experiment of simply excising the diseased part, the knee-joint, and retaining the foot and leg. This he did so successfully that, to use his own words, the patient several years after the operation 'made several voyages to sea, in which he was able to go aloft with considerable agility, and to perform all the duties of a seaman, that he was twice shipwrecked, and suffered great hardship without feeling any further complaint in that limb.' This was a crucial test of success that should have stamped the operation as one of the greatest surgical triumphs of the time, but, like so many other great strides taken in that age of extreme vivification, it was in advance of its fellows and was destined to be arrested for the better part of another half-century." The name of Harry Parke is professionally connected with two celebrated duels which took place in Liverpool. One was the affair between Major Brooks and Colonel Bolton. The parties had been arrested and bound over to keep the peace on one occasion, and before the year elapsed the Major publicly insulted Colonel Bolton in open day in Castle-street, a challenge from Colonel Bolton being the result. The twelve months' bond expired on Dec. 20th, 1805, and on the evening of that day the meeting took place in a field near Fairclough-lane, then a quiet rural road leading from the top of Pembroke-place to Low-hill. The spot must have been very near the site of St. Jude's Church. Major Brooks was accompanied by Mr. Forbes, and Colonel Bolton had Mr. Harris for his second. Mr. Parke was taken up by Colonel Bolton in his carriage as he passed his door. When they arrived on the ground it was so dark that they could not see to load the pistols. Candles were therefore procured; and here in the dreary, cold December night the tragedy proceeded to its *dénouement*. What a scene for the pencil of a Salvator

Hosted by Google

Rosa! The generous, public-spirited, kind-hearted British merchant, Colonel Bolton, who was actually the benefactor of the man who had insulted him, compelled by the "code of honour" of the day to imperil his life because the person whom he had fostered and cherished chose to treat him with base ingratitude. Nemesis, however, claimed her victim. The Major fired first without harming the Colonel, who returned the shot, hitting his opponent in the eye and killing him on the spot. The fatal report might have been heard at the Major's house, which stood at the corner of Daulby-street, not more than 200 yards distant. At the coroner's inquest a verdict of "wilful murder" was found; but no prosecution was ever instituted, public opinion being entirely in favour of Colonel Bolton. The other affair was of an earlier date. Lieutenant Sparling, of the 10th Regiment of Dragoons, was paying his addresses to Miss Anne Renshaw, daughter of Rector Renshaw, who resided in Bold-street. An anonymous letter was sent him reflecting on the character of the young lady's family. Although he stated on his trial that he discredited the greater part of the statements, yet enough remained to induce him to withdraw from his engagement, which he did by a letter to Mr. Renshaw. This led to a very bitter correspondence between the parties, and Lieutenant Sparling went abroad for some months. Whilst he was away rumour and gossip, of course, were rife. Mr. Grayson, the young lady's uncle, felt the insult very warmly. He was an entire stranger to Lieutenant Sparling, but did not hesitate to publicly brand him as a scoundrel and a villain, which ultimately led to a challenge from Sparling. The parties met about seven on Sunday morning, Feb. 26th, 1804, opposite the Old Chapel in Toxteth Park, and thence proceeded down the retired valley of the Dingle. Lieutenant Sparling's second was Captain Colquitt, R.N. (Glorious Sam, as he has been called), of the frigate *Princess;* Mr. Grayson's Dr. Macartney, a physician of eminence in the town. Harry Parke was also in attendance, but stated on the trial that he did not know for what purpose he was taken to the ground. At the first fire Grayson fell mortally wounded. Lieutenant Sparling and Colquitt were tried at Lancaster Assizes before Sir Alan Chambre, the result being an acquittal for both.

In the month of February, 1798, the people of Liverpool voluntarily subscribed £17,000 to enable the Government to meet the enormous expenses of the war. Among the subscribers were Henry Parke, who put down £100, James Gerard (probably the medical man), £50, and Dr. Worthington, £50.

BUBONIC PLAGUE IN BOMBAY.

THE Secretary of State for India has received the usual weekly telegram from the Governor of Bombay. It embraces the week ending March 19th. Summarily stated, it reports that the number of deaths from plague returned in that city amounted to 488; that less opposition was shown on the part of the natives in Poona and Karachi to the application of measures of prevention and disinfection; and that large numbers of people (3296) were being inoculated with Haffkine's lymph. The deaths from plague in Karachi during the week were 202. The disease has established itself at Haidarabad and Sukkur, and there are suspected cases at Shikarpur. The preventive measures generally adopted are essentially those which are enforced at Karachi. Inoculations for plague have begun in the last named place, and in Phana, Surat, Ahmedabad, and Poona. Great opposition is manifested at Bombay, in the native town, to the segregation of plague cases, and some rioting has taken place; and a strong deputation has also protested on the part of the Mohammedans against the enforcement of segregation orders. There cannot be any doubt, however, that the prompt segregation of infected cases is a most essential and urgent measure in dealing with the disease, and it is to be much regretted that it was not adopted at the earliest stage of the epidemic, when there would have been some chance of stamping out the outbreak whilst it was still circumscribed within very narrow limits. And this brings us to a matter about which strong opinions are held in Bombay—viz., as to the want of administrative management and organisation shown by the authorities at the beginning of the epidemic and to the extremely weak and ineffective way in which the municipal body in particular dealt with the matter. It was from no want of warning and early and accurate information as to the nature of the disease and the best and only way that it could be encountered. They had a medical committee to advise them, and the benefit of the best advice on the part of officers of the Indian Medical Service and other members of the medical profession to guide them. As it was the preventive measures that were recommended at an early stage of the disease, but not acted upon, had all to be adopted at a much later date when the plague had succeeded in getting a firm foothold in the city and created a panic, with the consequent exodus and risk of its spread to other places. Opposition arising from ignorance and caste prejudice was to be expected, and had in any case to be encountered sooner or later; but it made all the difference if it were encountered sooner rather than later. What is the line of action that has to be taken in all epidemic disease? It is twofold. To seek by hygienic measures to render a population as far as practicable immune in case of invasion of disease and to isolate at once those cases in which the disease declares itself. Of course, these principles of action are not always easily realised; but if we may judge from all we hear and read of local and municipal government in Indian cities, it is most feeble and ineffective and altogether unfitted for dealing with matters of this kind. Action requires to be based upon experience and clearly reasoned out principles, and adopted with more reasonable promptitude than was the case in India. Several excellent communications and articles have appeared from time to time in reference to this matter in the *Times of India*. Segregation, disinfection of vacated houses, measures for thinning an overcrowded population, the destruction by fire of miserably insanitary dwellings, and the creation of air spaces, wholesale cleansing, house-to-house visitation wholesale cleansing—all these things had to be adopted in the end. It is only right to add that these measures were, we understand, represented by the local medical authorities long before they were carried out. It may be urged that it is no good reverting to them now, but what happened in Bombay in regard to this epidemic is what has so often happened before, and probably will again, for people will have it so. We quite appreciate, however, the great difficulties and responsibilities of such a situation, especially in the case of a big Indian city with its different races, religions, and castes, and we gladly recognise that the Bombay Government when it grappled with the situation in earnest did all that it possibly could. The epidemic has been the cause of a large loss of life, and Europeans have not by any means been altogether spared; it has paralysed for a time the trade and caused a large financial loss, but it has not been without its compensations in that it has awakened the attention of all to the importance of public hygiene and given rise, let us hope, to the introduction of many salutary changes in other cities than Bombay.

The medical profession and the public will have learnt with regret that Professor Hankin is stated to have contracted the disease, but the attack proved to be a mild one, and he is fast recovering, if he be not already quite well.

We recommend to the notice of our readers an article from the pen of a particularly well-informed local correspondent on the sanitary condition of Bombay. It is printed on page 915 of this issue.

M. HAFFKINE AND HIS ANTITOXIN TREATMENT OF PLAGUE.

It is stated in the *Pioneer Mail* of the 4th inst. that M. Haffkine is now ready to administer his antitoxin, which has been under preparation at Sewree, in cases of plague of recent occurrence which may be reported to him by medical men in a position to ascertain that the patient has shown symptoms within a definite period not exceeding forty-eight hours. The antitoxin has been tested in very advanced cases at the Arthur-road Hospital and elsewhere, and also in a series of cases which permitted comparison between patients in a dangerous state subjected to antitoxin treatment with others of the same group in milder attacks and left to ordinary treatment, and the attempt, though not successful in every case, gave results undoubtedly favourable to the treatment.

PASTEUR MEMORIAL LECTURE.

A SPECIAL meeting of the Chemical Society was held on Thursday evening, March 25th, when Professor Percy Frankland, F.R.S., delivered the Pasteur Memorial Lecture.

Professor Percy Frankland commenced his discourse by pointing out how the consideration of Pasteur's work was a subject specially befitting the Chemical Society, inasmuch as he owed the training which enabled him to master so many and such various problems to the rigorous discipline in early years which he underwent in the pursuit of chemistry. His first laurels were won in chemical science, and the epoch-making discoveries which he made as a student and assistant at the famous École Normale have stimulated researches in, and practically founded, that fascinating and important branch of investigation known as stereo-chemistry. Perhaps the most conclusive and eloquent testimony which we can have to the profound importance of Pasteur's researches in this direction is the tribute paid to them by his greatest follower, Emil Fischer, who acknowledged that, despite the immense amount of work which has since been carried out, "there is hardly a new fact of fundamental importance which has been added to his discoveries."

Removed to Lille, Pasteur entered upon those fermentation studies which he followed with such brilliant success over a period of twenty years. In this field of enquiry he had his first passage of arms with the great Liebig; it is needless to say that Pasteur emerged victorious, and the vital has replaced that chemical theory of fermentation processes which was advanced so eloquently by Liebig and other leading men of science of the day. The story of the famous spontaneous generation controversy was told, and it was pointed out how Pasteur was unconsciously preparing himself for the great work with which his name will always be associated—the inauguration of the modern system of preventive medicine. Already in his researches on diseases in silkworms he was attracted by the study of contagion, and the valuable experience he gained in this work may be gathered from the fact that in later years, when anyone presented himself and begged the privilege of working in his laboratory, he used to ask them if they had read his volume on silkworm diseases, and tell them that that was the best preparation they could have for the work which they would be likely to have to undertake. But besides Pasteur's growing interest in the bacteriological elucidation of diseases he was led to embark upon it himself from a growing conviction that the hands into which it had mainly fallen were more likely to damage than benefit the good cause, and Professor Frankland then went on to relate how Pasteur threw himself at the ripe age of fifty-five years with all the enthusiasm of youth into the subject of disease and its prevention, commencing with the study of anthrax. But even while carrying on elaborate experiments on this disease he was turning in all directions for material to extend his researches on pathological phenomena. He walked the hospitals armed with sterile vessels to collect morbid products, he cultivated the staphylococcus pyogenes from boils on the person of one of his assistants, he visited the Maternity Hospital and discovered the streptococcus pyogenes, asserting it to be the cause of puerperal fever. In this connexion an amusing incident was related by the lecturer, who described how Pasteur entered during a lively discussion which was being carried on at the Academy of Medicine as to the origin of puerperal fever, and after listening for some time, unable to restrain himself any longer, he rose and told the medical men present that what caused the disease was nothing to do with what they had been saying, that, on the contrary, it was the medical man himself who carried the microbe of the disease from one patient to another, and when the speaker replied that he was afraid they would never discover that microbe, Pasteur rushed to the blackboard and drew the streptococcus, saying, "Tenez, voici sa figure." The stupefaction and surprise of his audience is more easily imagined than described.

From the etiology of diseases such as anthrax, fowl cholera, swine fever, Pasteur passed on to the consideration of the means whereby they could be combated. The great achievement of Jenner—an achievement which, Professor Frankland reminded his audience, Herbert Spencer had pointed out was rewarded by a grateful country in the shape of a begrimed statue hidden away in an obscure corner of the Kensington-gardens frequented chiefly by nursemaids and perambulators,—had long been dwelt upon by Pasteur, and he cherished the ambition of securing an immunity for those diseases for which the nature of the viruses had now been made known similar to that which Jenner had secured in the case of small-pox. How he came upon his first "vaccine"—viz., that of fowl cholera—through his cultures of the microbe of this disease having suffered such degeneration during a vacation that they were found incapable of infecting fowls, and how Pasteur, who never neglected any fact, was led to re-inoculate the fowls which had resisted the infection with these weakened cultures to see if they could take the disease, and thus discovered to his intense satisfaction that they had been rendered immune, Professor Frankland described in detail. The magnificent triumph which followed the discovery of a "vaccine" for anthrax and other diseases was, however, if possible, eclipsed by the production of a cure for rabies.

The public expression of gratitude for this great discovery took the form of a public subscription, which rendered possible the foundation of the now famous Institut Pasteur. The creation of such an institute had long been cherished as a dream by its first director and great master, and its realisation was the delight of the few remaining years of his life; and here, under the auspices of Duclaux, Roux, Chamberland, and Metchnikoff, the sacred fire kindled by *le grand maître* is still burning, and long (concluded Professor Frankland) may this flame be fed within the temple where rests that hero of science whose great ambition was to be able in his last hour to pronounce the words, so simple in their form, so boundless in their aspiration, "*J'ai fait ce que j'ai pu.*"

THE APOTHECARIES' HALL OF IRELAND AND THE GENERAL MEDICAL COUNCIL.

ON Monday, Feb. 22nd, a Committee of the Privy Council, consisting of the Duke of Devonshire, Lord Rathmore, Lord Macnaghten, and Lord James of Hereford, heard the appeal of the Apothecaries' Hall of Ireland against the decision of the General Medical Council in refusing to appoint examiners to assist in the qualifying examinations held by the Hall.

Mr. Haldane, Q.C., and Mr. B. Stephen Foster appeared for the Apothecaries' Hall, and Sir Robert Reid, Q.C., M.P., and Mr. Muir Mackenzie appeared for the General Medical Council.

For the appellants it was urged that the decision of the General Medical Council would, unless over-ruled by the Privy Council, practically put an end to the existence of the Apothecaries' Hall.

Previously to 1886 the Apothecaries' Hall had the power of examining and registering candidates under the Medical Act. The Act of 1886 gave the General Medical Council power to see that a sufficient standard of efficiency was maintained at any qualifying examination. The General Medical Council had reported that they were dissatisfied with a certain part of the examination held by the Apothecaries' Hall on several occasions and refused to appoint examiners, which was also a part of the powers conferred upon the General Medical Council by the Act of 1886.

After considerable discussion, the Duke of Devonshire intimated that the decision of the Committee would be communicated to the parties in due course.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6381 births and 3936 deaths were registered during the week ending March 20th. The annual rate of mortality in these towns, which had been 18·1 and 18·6 per 1000 in the two preceding weeks, further rose last week to 18·7. In London the rate was 17·9 per 1000, while it averaged 19·2 in the thirty-two provincial towns. The lowest rates in these towns were 9·6 in Derby, 12·0 in Croydon, 12·3 in Norwich, and 12·9 in Brighton; the highest rates were 23·4 in Manchester, 24·5 in Wolverhampton, 25·4 in Preston, and 26·9 in Salford. The 3936 deaths included 344 which were referred to the principal zymotic diseases, against 331 and 334 in the two preceding weeks; of these,

Hosted by Google

113 resulted from whooping-cough, 87 from measles, 61 from diphtheria, 32 from diarrhœa, 28 from scarlet fever, and 23 from "fever" (principally enteric). No death from any of these diseases was recorded last week either in Wolverhampton or in Leicester; in the other towns they caused the lowest death-rates in Croydon, Brighton, and Oldham, and the highest rates in Blackburn, Cardiff, Bolton, and Salford. The greatest mortality from measles occurred in Manchester, Cardiff, Gateshead, Bolton, and Salford; and from whooping-cough in Salford, Bristol, Swansea, Burnley, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 61 deaths from diphtheria included 37 in London, 4 in Birmingham, 4 in Liverpool, 3 in Huddersfield, and 3 in West Ham. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three large towns. There were 29 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 20th, against 43 and 30 at the end of the two preceding weeks; 2 new cases were admitted during the week, against 18, 6, and 0 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2622, against 2817, 2745, and 2685 on the three preceding Saturdays; 206 new cases were admitted during the week, against 237, 211, and 218 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 307 and 344 in the two preceding weeks, declined again to 317 last week, and were 206 below the corrected average. The causes of 56, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Nottingham, Leeds, Hull, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the five preceding weeks from 28 8 to 23·1 per 1000, rose again to 23·3 during the week ending March 20th, and exceeded by 4·6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·0 in Leith and 20·6 in Edinburgh to 24·5 in Paisley, and 32·4 in Perth The 693 deaths in these towns included 33 which were referred to measles, 33 to whooping-cough, 15 to diarrhœa, 11 to "fever" (principally enteric), 9 to scarlet fever, and 5 to diphtheria. In all, 106 deaths resulted from these principal zymotic diseases, against 96 and 83 in the two preceding weeks. These 106 deaths were equal to an annual rate of 3·6 per 1000, which was 2 0 per 1000 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 30 and 27 in the two preceding weeks, rose again to 33 last week, and included 21 in Glasgow and 12 in Edinburgh. The deaths from whooping-cough, which had been 36 and 29 in the two preceding weeks, rose to 33 last week, of which 24 occurred in Glasgow, 5 in Edinburgh, and 3 in Perth. The 11 deaths referred to different forms of "fever" considerably exceeded the number recorded in any recent week, and included 8 in Glasgow. The fatal cases of scarlet fever, which had been 5 in each of the two preceding weeks, rose to 9 last week, of which 2 occurred in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. Of the 5 deaths from diphtheria 3 were registered in Glasgow and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 203 and 152 in the two preceding weeks, were 155 last week, and exceeded by 39 the number in the corresponding period of last year. The causes of 38, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 45·2 and 39·1 per 1000 in the two preceding weeks, rose again to 40·4 during the week ending March 20th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 40·7 per 1000, the rate during the same period being 18·6 in London and 22·3 in Edinburgh. The 271 deaths registered in Dublin during the week under notice exceeded by 9 the number in the preceding week, and included 74 which were referred to the principal zymotic diseases, against 59 and 61 in the two preceding weeks; of these, 46 resulted from measles, 20 from whooping-cough, 4 from diarrhœa, 2 from scarlet fever, 2 from "fever," and not one either from small-pox or diphtheria. These 74 deaths were equal to an annual rate of 11·0 per 1000, the zymotic death-rate during the same period being 1·5 in London and 3·6 in Edinburgh. The fatal cases of measles, which had been 44 and 43 in the two preceding weeks, rose again to 46 last week. The deaths referred to whooping-cough, which had been 21 and 9 in the two preceding weeks, rose again to 20 last week. The two fatal cases of scarlet fever corresponded with the number recorded in the preceding week. The 271 deaths registered in Dublin last week included 55 of infants under one year of age, and 49 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were below those recorded in the preceding week. Seven inquest cases and 6 deaths from violence were registered; and 65, or nearly a fourth, of the deaths occurred in public institutions. The causes of 16, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL R EXHAM, Surgeon-Majors E. North, J. M. Jones, and H. L. Battersby, Surgeon-Captains C. W. Reilly, T. Birt, and H. E. Winter have arrived home from India in the transport *Victoria*.

Surgeon-Major J. J. C. Donnett has been appointed Special Sanitary Inspecting Officer, Poona Cantonment. Surgeon-Major N. G. Macpherson has been appointed to the Army Medical Department at the War Office. Surgeon-Major Tidbury has been transferred from Cork to Portsmouth.

Surgeon-Captain George M. Dobson, M.B., to be Surgeon-Major.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain J. J. Bourke and Surgeon-Lieutenant F. A. L. Hammond, whose services have been placed at the disposal of the Chief Commissioner, are appointed Inspecting Medical Officers under the rules made under the Epidemic Diseases Act, 1897, and are posted to the stations of Itarsi and Nagpur respectively. Surgeon-Lieutenant H. St. J. Fraser, whose services have been placed at the disposal of the Chief Commissioner, is posted to Hoshangabad for employment on famine duty. Surgeon-Lieutenant C. M. Mathew, whose services have been placed at the disposal of the Chief Commissioner, is posted to Raipur for employment on famine duty.

To be Surgeon-Colonel: Brigade-Surgeon-Lieutenant-Colonel George Bainbridge, M.D., Bombay Establishment (dated Oct. 4th, 1896). To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon Lieutenant-Colonel Charles Henry Joubert, Bengal Establishment (dated Sept. 1st, 1896). To be Surgeon-Lieutenant-Colonel: Surgeon-Major Charles Henry Beatson, Bengal Establishment (dated Sept. 30th, 1896). Surgeon-Lieutenants to be Surgeon-Captains (dated Jan. 29th, 1897)—*Bengal Establishment:* George Lamb, Henry Burden, John Fisher, Edward Surman Peck, Charles Harford Evans, Stanley Arthur Harris, Ewan Cameron MacLeod, and Charles Thomson. *Madras Establishment:* Alfred Eugene Berry and Herbert St. John Fraser. *Bombay Establishment:* Bernard Henry Frederick Leumann and Hugh Bennett.—*London Gazette.*

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeons: A. G. P. Gibbs to the *Victory*, for the *Malacca*; W. G. K. Barnes to the *Undaunted*; J. J. Dinnis to the *Edgar*; and J. Sugrue to the *Australia*. Surgeons: C. H. Rock to the *Undaunted*; D. J. P. McNabb to the *Edgar*; E. G. E. O'Leary to the *Research*; John Grant to the *Pembroke*, and afterwards to the *Pelorus*; Sidney T. Reid to the *Hibernia*; and John W. Slaughter to the *Victory*, for the *Malacca*, on the voyage home.

HONOURABLE ARTILLERY COMPANY OF LONDON.

The under-mentioned officer resigns his commission:—Surgeon-Captain H. G. Read (dated March 24th, 1897).

Hosted by Google

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain H. W. Roberts to be Surgeon-Major.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant J. T. Simpson to be Surgeon-Captain on increase of establishment.

VOLUNTEER CORPS.

Artillery: 2nd Kent: Surgeon-Major F. Smith, M.D., to be Surgeon-Lieutenant-Colonel. 1st Dorsetshire (Southern Division, Royal Artillery): Surgeon-Lieutenant Hubert Houssemayne Du Boulay resigns his commission, and is appointed Lieutenant. 1st West Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Captain John Nightingale resigns his commission, and is appointed Second Lieutenant. *Rifle:* 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant C. Boyd to be Surgeon-Captain. 5th Volunteer Battalion the Cheshire Regiment: Surgeon-Major W. R. Dambrill-Davies to be Surgeon-Lieutenant-Colonel. 14th Middlesex (Inns of Court): Surgeon-Lieutenant C. J. Arkle, M.D., to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Captain J. E. Squire, M.D., to be Surgeon-Major on increase of establishment. Surgeon-Lieutenant H. D. Buss to be Surgeon-Captain.

THE HEALTH OF THE FRENCH ARMY IN 1896.

The medico-statistical report issued annually by the French War Minister has made its appearance, as usual, in the *Journal Officiel*, and, generally speaking, its contents may be said to show that the advance of the army towards sanitary perfection, which of late years has been very conspicuous, was adequately maintained during the past twelvemonth. In 1887, ten years ago, the total number of men with the colours was 480,672, and among them 3319 deaths took place, equal to 6·9 per 1000; but in 1896, although the average strength had risen to 546,500, the deaths only numbered 2900, or 5·3 per 1000. This happy result is chiefly due to the measures that have been adopted for purifying the water-supply. Formerly, many garrisons—notably those at Lure, Évreux, and Châteaudun—used to be well-nigh decimated by constantly recurring outbreaks of typhoid fever, but now they enjoy what the Minister describes as "absolute salubrity." The evidence thus afforded being conclusive, it has been decided to acquire six more sterilising apparatuses in order that they may be permanently installed wherever the drinking water is open to suspicion. According to this system of purification the water is rendered sterile by means of steam at high pressure, and the appliances are said to be at once simple in construction, durable, economical, and easily worked. Whilst thus eulogising the latest device for combating water-borne disease, General Billot by no means seeks to minimise the "incontestable advantages" of the Pasteur Chamberland filter. The efficacy of the latter admirable invention was placed beyond doubt by the unanimous chorus of approval from every garrison, large or small, where it was used; but the sanitary authorities nevertheless felt bound to take advantage of the new system which, after several years of experiment under their own close supervision, had gradually been brought to perfection. Turning from the prevention of disease to its incidence, the Minister is able to announce the steady decrease of small-pox amongst the troops. In 1876-77-78 the number of cases exceeded 1000 annually, and the deaths to be deplored were respectively 127, 92, and 98. In 1895 there were only 61 cases of small-pox in the whole army, with 6 deaths; while last year of 57 cases only 2 proved fatal. It is owing to re-vaccination that the soldiers were safeguarded while on service in Africa, Madagascar, and Tonkin, surrounded as they were by a native population, amongst whom the scourge is both endemic and deadly. As regards "croup," the fatal cases have been reduced by more than a half. All military hospitals, as well as every military centre, no matter how small, in France and Algeria is now daily furnished with the special instruments and appliances required for anti-diphtheritic inoculation, the serum being supplied and freely renewed whenever needed by the Pasteur Institute. The sequel to this enlightened procedure is plainly discernible. In 1893 the mortality from "croup" in the French army amounted to 64; by 1895 it had fallen to 24; and in 1896 the number of deaths was only 22. Unfortunately there are other diseases which continue to exact numerous victims. Scarlet fever, measles, and influenza are still extremely frequent; but mixing as the soldier does in civil life while on leave of absence it is difficult to contend against these products of insanitation. The reservists, too, are a fruitful source of infection; but in spite of all obstacles the struggle with preventable mortality is waged with unabated zeal. "It is impossible to conceal from oneself the fact," says the Minister in conclusion, "that every cause of insalubrity in barracks has its reflection in augmented bills of sickness and mortality. This was well exemplified at Dijon when influenza was prevalent, and also quite recently in the scarlet fever epidemic at Gerardmer. It is likewise impossible to conceal from oneself the fact that all amelioration in the installation of these same barracks has its reflection in very considerable expenditure, and that my department is constrained to keep within those limits of the budget that are laid down annually."

THE WRECK OF THE "WARREN HASTINGS."

We called attention some time ago to this subject and to the fact that it had most deservedly attracted the notice of the Queen. We may be excused for referring to it again, for it is one of which the nation and the Army may well feel proud. It has since been made the subject of a special Army order in which the Commander-in-Chief expresses his great gratification "in making known to the Army the substance of a report received from the General Officer commanding at the Mauritius recording the remarkable courage and exemplary discipline displayed by the troops, under the most trying circumstances, on board the Royal Indian Marine troopship *Warren Hastings*, when that ship, steaming full speed, struck the rocks during a pitch-dark night and was wrecked near the village of St. Philippe, in the Island of Réunion, at 2 20 A.M. on Jan. 14th last. The troops on board consisted of the headquarters and four companies of the 1st Battalion King's Royal Rifle Corps, four companies of the 2nd Battalion York and Lancaster Regiment, and a detachment of the Middlesex Regiment." Lord Wolseley, after quoting from the report of Commander Holland, the officer in command of the *Warren Hastings*, that the behaviour of the troops throughout was beyond all praise, concludes his order as follows: "The Commander-in-Chief is proud of the behaviour of the troops during this trying time; he regards it as a good example of the advantages of subordination and strict discipline, for it was by that alone, under God's providence, that heavy loss of life was prevented. The Commander-in-Chief cannot close this order without expressing his admiration of the coolness, courage, and resource shown by Commander Holland, and sympathy with him and his brave officers."

PLAGUE ON A TRANSPORT.

The announcement that the transport *Dilwara* is being detained at Suez, owing to the occurrence of a fatal case of plague on board the vessel after she left Bombay, will tend to accentuate the supposition that if this disease is introduced into England it is not at all unlikely that troops returning from India may be responsible for its introduction. It therefore behoves the naval and military authorities to take every possible precaution to ensure that all troopships coming from infected ports shall be carefully dealt with in accordance with modern notions, and in harmony with the proceedings adopted by our best-equipped and best administered port sanitary authorities. We are not aware that up to the present the military and naval authorities have made any arrangements independently of the port sanitary authorities, for dealing with cases of plague or suspicious "pestis minor"; but we have heard that they have approached the Southampton port sanitary authority with a view to the isolation of any cases of plague which may be brought to that port. As Southampton is at present the port at which the majority of our troopships arrive it is obviously important that adequate arrangements shall be made beforehand, and that there shall be a thorough understanding as to what steps are to be taken to deal without delay with an infected troopship. The Southampton port sanitary authority is, we believe, one of the best equipped in the kingdom and is well able to afford the necessary assistance. Quarantine is dead in so far as the national method of dealing with infected vessels is concerned, and all vessels must be dealt with on similar lines if England is to maintain a consistent attitude in the eyes of the world.

A VOLUNTEER MEDICAL OFFICER WANTED.

On the occasion of the presentation of prizes to the 3rd Essex Volunteers on the 13th inst., at Portway, Lieutenant-Colonel Henry Palmer, 3rd Volunteer Battalion the Essex Regiment, took occasion to mention that no medical gentleman in West Ham had applied for a commission in the 3rd Essex. The 1st Essex had its medical officer, the 3rd Essex had none.

VOLUNTEER MEDICAL OFFICERS AND THE WAR OFFICE.

A correspondent writes to us under date March 22nd, a letter, in which he propounds the question: Is the Volunteer Medical Service either loyal to the medical profession itself or to the Army Medical Department in doing professional work for nothing? "I am inclined to think," he says, "that the medical officer is decidedly wrong in giving his services to either his country or to individuals for nothing. In the latter case it may be but right that he should retain his individual liberty, but in the former case he has given himself away, as in a number of corps he pays an annual subscription. Is the profession right in devoting a very considerable part of its time to the working up of bearer companies, each of which occupies the entire attention of at least one medical officer for probably four or five hours a week teaching both by drill and lectures. This year there has been a very important addition made to the duties of medical officers—i.e., the examination of recruits. This examination, though not intended to be anything like as thorough as for recruits for the regular forces, still takes some time, and also necessitates the attendance of a medical officer at headquarters weekly."

THE HEALTH OF THE ARMY IN INDIA.

Surgeon-Major Whitehead, in the report of the departmental committee on venereal disease, sums up his experience during the five years of his appointment as Assistant Professor of Military Surgery at Netley, during which he had unrivalled opportunities of studying the question of the prevalence of syphilitic disease among our troops, with the following conclusions: "(1) That the disease is more prevalent at present than formerly among foreign invalids; (2) that the type is more malignant; and (3) that the health and efficiency of the soldier are in many cases absolutely ruined by this disease, and even if he so far recover after a bad attack as to return to duty there is a great probability of his again breaking down." When we consider that this contagious and hereditary disease is largely preventable we may well urge the extreme importance of some measures being taken to put a stop to the present scandalous state of affairs.

REVISED SCALES OF PAY FOR THE ARMY MEDICAL STAFF IN INDIA.

The *Times of India* of the 6th inst. states that the revised scales of pay approved by the Secretary of State for the Army Medical Staff in India and certain grades of the Indian Medical Service will come into effect from April 1st. An Army circular will shortly be published showing the new rates.

The transport *Victoria* arrived on the 18th inst. She brought 320 patients for the Royal Victoria Hospital, Netley.

The transport *Dilwara* left Bombay on the 11th inst. with 293 invalids for Netley. Her arrival will probably be postponed in consequence of a case of bubonic plague having occurred on board.

Dr. S. Wilks, President of the Royal College of Physicians, Sir Dyce Duckworth, Sir Wm. Priestley, and Dr. John Anderson visited the Royal Victoria Hospital, Netley, on Saturday last, in connexion with the inquiry which has been instituted with regard to the prevention of contagious diseases among the men of the Army in India.

CARDIFF PORT SANITARY AUTHORITY. — The medical officer of health for the Cardiff port sanitary authority has just issued his report for 1896. Dr. Walford estimates the floating population of the port to be 7000, and states that during the year 6222 vessels were inspected; of these 5271 were in a good or fair condition and 951 in a more or less insanitary state. The systematic inspection of shipping in the Bute and Penarth Docks was efficiently performed by the chief inspector and his assistants. In only five cases was it necessary to take legal proceedings. Nine patients were admitted to the infectious diseases hospital, one of the cases terminating fatally.

Correspondence.

"Audi alteram partem."

"THE MEDICAL STAFFS OF HOSPITALS AND HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—Mr. Horder assumes that I was in error in stating that Sir William Fergusson's committee recommended that medical officers attending the out-patients should be paid. I have before me as I write the report of the committee appointed to inquire into the subject of Out-patient Hospital Administration in the Metropolis in 1871, signed by Alfred Meadows, M.D., chairman, J. H. Stallard, M.B., and Heywood Smith, M.B., honorary secretaries. The report states: "The following resolutions embody in brief form the conclusions at which your committee have arrived and which they recommend for adoption." No. 6 of these resolutions runs as follows: "That the governors of hospitals ought in all cases to provide some honorarium for the staff of the out-patient department." You will see, therefore, that Mr. Horder, and not myself, is in error, and I am rather surprised to find that he has not procured a copy of the report in question, and that he is evidently not familiar with its terms.

On another point raised by Mr. Horder I desire to impress upon the medical profession that so long as we have honorary medical staffs attached to our great hospitals—that is, unpaid staffs—so long will the hands of the managing committees be tied, so far as initiative is concerned, in the work of reforming the out-patient departments unless the medical profession commence proceedings by making representations to the managers. This fact makes me strongly in favour of the abolition of all honorary medical service, at any rate so far as the great London hospitals are concerned. I am sure on the grounds of economy, although it might cost the hospitals £60,000 a year to pay for the necessary medical service, such a step would in the end tend to reduce rather than to increase the average cost per bed. The medical profession now have a unique opportunity, which may not recur, of conferring together and formulating a definite policy in regard to out-patient relief and other matters of pressing importance affecting the administration of our hospitals. I wrote my letter because I realised this position of affairs, and wished, if possible, to induce the medical profession in its own interests, and in the best interests of the hospitals and all connected with them, to take up a strong position after due deliberation and conference by formulating a policy in regard to these matters. The governors and committees would thus be placed in a position to institute every reform, which may be found desirable or necessary in the best interests of the patients, the profession, and the public. I desire to thank Mr. Horder, and through him the members of his committee, for their statesmanlike determination to postpone for a time the public conference which it was proposed to hold this summer.

The writer of the leading article in THE LANCET of March 20th, no doubt unintentionally, does me less than justice. I have never stated, nor do I hold the opinion, that "the Hospital Sunday Fund and the Prince's Fund have at present but little responsibility for the use of what they collect." On the contrary, it is because I am deeply impressed with the responsibility attaching to the distribution of these funds, and to the paramount necessity of providing that our voluntary charities shall be as free, as it is humanly possible to make them, from all preventable abuses, that I ventured to write you the letter which appeared in THE LANCET of March 13th, and to state the grounds upon which I gave my entire support to your proposal, that a conference should take place in the near future of the members of the honorary medical staff, attached to every hospital of repute in the metropolis. I joined issue with Dr. Glover on the out-patient question, so far as the Hospital Sunday Fund was concerned, because I realise, that without such a conference not only the Hospital Sunday Fund, but the hospital committees throughout London, must remain practically powerless to enforce the reforms in the out-patient departments, which he has so much at heart. Premature action and an attempt at interference without the necessary authority to enforce needful reforms, are calculated to prove

Hosted by Google

more harmful than helpful. That is why I ventured to deprecate putting the cart before the horse, by moving the Hospital Sunday Fund to make representations, before we were clear that those representations could be accepted by the hospital committees with the support of their medical staffs; for with the medical staffs, as I have already stated, the chief responsibility for the present state of affairs in reality rests. I am, Sirs, your obedient servant,

HENRY C. BURDETT.

The Lodge, Porchester-square, W., March 22nd, 1897.

To the Editors of THE LANCET.

SIRS,—With reference to the letter of Mr. T. Garrett Horder in THE LANCET of March 20th I should be obliged if you would allow me to say that at this hospital we have for many years made inquiries into the circumstances of the out-patients. May I also add that a medical officer sifts the cases before they are seen by the assistant physician or assistant surgeon.

I am, Sirs, yours faithfully,

C. L. TODD, Secretary.

St. George's Hospital, S.W., March 24th, 1897.

"HOSPITAL ABUSE: THE LEEDS WORKPEOPLE'S HOSPITAL FUND."

To the Editors of THE LANCET.

SIRS,—As a general practitioner of medicine for seventeen years in Leeds, during which time I have seen a great deal of the working-man patient, also having as a student attended at the Leeds Infirmary, I have acquired some little experience in the subject discussed by THE LANCET Commissioner, which experience is directly opposed to that of Dr. Eddison and to that of Mr. Jowitt. The working man, I believe, subscribes to the infirmary 1*d.* a week, or something like 4*s.* per year. Now, very few lodges pay per head so much as that for medical and surgical attendance—the club patient can for the sum of 3*s.* 6*d.* per annum command attendance at his own home and medicine, &c. Naturally he supposes that the larger amount paid to the infirmary gives him equal rights at that institution, and I have heard this said not once but often, so often, indeed, that I was astonished that any one should make an assertion to the contrary. I have known the case of a woman possessed of independent means, able to pay 50 guineas for a surgical operation, become an in-patient of the Leeds Infirmary for the purpose of an operation; she was not a resident in Leeds, she had no claim upon Leeds, and the surgeon who performed the operation robbed himself of something like 50, or it may easily have been 100, guineas. Moreover, her friends considered her as a private patient and so termed her. In another town a lady of fortune, who spends large sums in charity, fell from a bicycle, costing probably £30, breaking her leg. She was treated in an infirmary, to which institution she presented £100 on leaving, which money I affirm was rightfully the fee of some practitioner, though perhaps no medical man would have had such a large amount of gratitude shown to him. I have known a man treated at the Leeds Infirmary for fractured arm throughout the entire course, which man lived in a good house in a good neighbourhood—such a district, in fact, where all consulting surgeons and physicians ask for fees on the higher scale. In my student days I actually extracted teeth from people I knew could afford a dentist's fees. Little, perhaps, they knew it was a 'prentice hand that held the forceps! I have known a woman in good circumstances leave her rings and jewellery at home, so advised to do by her friends, when it was necessary to consult a leading Leeds surgeon at his rooms—nay, more, she dispensed with her brougham, using the humble cab; and this course was adopted to save one guinea, the idea being that she would be charged two guineas if she appeared in her proper guise. The sufferers from trivial accidents requiring minor surgical operations are all urged to go to the infirmary. Persons even spend more in railway and cab fares than would be charged by ordinary medical men. It is obvious that those who will so spend from 2*s.* 6*d.* to 5*s.* are not those for whom a charitable institution is intended. I suppose all who subscribe—in the way of rates, at least—to the Leeds Workhouse have the right to claim a place there. Then why deny those who subscribe to the Leeds Infirmary the same rights? Both of these institutions are for the poor and sick. I do not wish my name and address to appear. I am, Sirs, yours truly,

LEEDS PRACTITIONER.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—May I point out that your correspondent who writes anonymously in favour of registration in THE LANCET of March 20th is extremely wide of the mark. He thinks, like the promoters of the Bill, that the magic of registration will efface the horrors he describes and, like Dr. Cullingworth, that the maladies of childbirth will cease to be; in fact, that we are on the eve of a parturient millennium. One of the staple arguments of registrationists is that the educated midwife will *send* for medical aid on the first approach of danger. This is a mere supposition. The "follower" of one of these women in this parish was required in 23 per cent. of her cases in 1892, and in 8 2, 2·5, 2 7, and 2 8 per cent. in 1893, 1894, 1895, and 1896 respectively. One woman died in her confinement, there was a death from miscarriage, and an infant was sacrificed through delay in a shoulder and funis presentation. I need not add to the list of casualties; and will only say, in conclusion, that a Bill which proposes to register *bonâ fide* midwives of two years' standing, which will include most of the existing "Gamps" and which still recognises the friendly neighbour's assistance, stands self-condemned. There is no provision at all for the after-nursing, which is the most vital part of the parturient function, and as it is perfectly evident that the qualified midwife will not act as an obstetric nurse under medical supervision I utterly fail to see how the Bill will benefit "the poor" if it become law; and if I had not had the promise of Mr. Skewes-Cox to have it referred to a committee of the House so that "all parties" may be heard I would long ago have offered it a more vigorous opposition. Dr. Cullingworth is a special pleader, and his recent address on puerperal fever is largely discounted by his attitude in this question and his more recent address to the promoters of the measure.—I am, Sirs, yours faithfully,

East Sheen, March 22nd, 1897. ALEX. MCCOOK WEIR.

THE COLONY FOR EPILEPTICS.

To the Editors of THE LANCET.

SIRS,—Will you allow us to make an appeal through the columns of THE LANCET on behalf of the colony established at Chalfont St. Peters by the National Society for Employment of Epileptics. Amidst the earnest efforts for the succour of the sick and afflicted which have so distinguished this country during Her Majesty's reign, one form of infirmity is still almost overlooked, and in England there are probably not less than 40,000 epileptics who lack the care which is bestowed upon their fellow sufferers amongst other nations. For both in Europe and America many institutions or settlements have been established on the lines of the famous "Colony of Mercy" at Bielefeld, in Westphalia, which affords a home for nearly 1400 epileptics. Under ordinary circumstances epileptics of the poorer classes live under conditions so unsuitable that in many instances they sink into a state of insanity and at last find refuge in the asylums. The object of the colony is to save them from this fate by taking them in hand at an earlier stage and enabling them to lead lives of usefulness and activity. The care of the insane is a heavy burden on the country, and the preventive methods of the colony will, we believe, be found in the long run to be economic as well as humane.

Amongst the numerous candidates waiting for admission to the colony, about one in ten drops out of the list every year through insanity or death, whilst at the colony itself, since its establishment nearly three years ago, only one death has occurred and only one patient has had to be transferred to an asylum. The average number of epileptics in residence at the colony has been twenty-seven. Besides the two homes at present in occupation at the colony, two others, the funds for which have been specially given, are in course of erection, and additional funds have been offered by generous friends, notably by Mr. Passmore Edwards, for the erection of several other homes, which will be commenced shortly. Within a year there will therefore, it is hoped, be accommodation at the colony for about 160 epileptics, men, women, and children. Even then the provision will be small in comparison with the need. But while the funds for building the new homes are provided, these great extensions will involve considerable

Hosted by Google

incidental outlay, for which as yet little provision has been made. A laundry will be needed for the female colonists and school accommodation for the children. The sewerage system will need extension, and the committee are of opinion that for the security of the colony when its numbers increase there must be a resident medical officer, for whom a house will have to be provided. It is estimated that on the most economical basis the outlay for absolutely necessary purposes will be £10,000, whilst for the extension of the colony on a scale really proportionate to the demand for admission a far larger sum would be needed.

Epileptics are received at the colony impartially from all parts of the kingdom, and we therefore appeal for help to the charitable public throughout the country, and we trust that during this memorable year the effort begun to help a suffering and hitherto almost neglected class of our afflicted brethren may be placed upon a footing sound, hopeful, and commensurate with their great necessities.

Contributions, which will be duly acknowledged, should be sent to the secretary, Mr. G. Penn Gaskell, at the society's offices, 12, Buckingham-street, Strand, London, W.C., or to the bankers, Messrs. Hoare and Co., 37, Fleet-street, London, E.C.—We are, Sirs, your obedient servants,

DEVONSHIRE.
HERSCHELL.
W. H. BROADBENT, M.D. Lond.
JAMES CRICHTON BROWNE, M.D Edin., F.R.S.
C. S. LOCH.

March 22nd, 1897.

THE RECENT DEBATE UPON VACCINATION AT THE EPIDEMIOLOGICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—As the brief report of my contribution to the discussion on vaccination at the Epidemiological Society which is given in THE LANCET of March 20th is calculated to convey an erroneous impression of my opinion on the subject of vaccinal injuries, I shall be obliged if you will allow me to make one or two corrections. 1. As regards vaccinal syphilis I stated that although every alleged case of invaccinated syphilis brought before the Commission which had occurred between the years 1889 and 1896 was subjected to a searching inquiry, not one stood the test of an investigation into all the circumstances. I did not state that all were cases of congenital syphilis. 2. It is not my opinion that all cases of vaccinal erysipelas result from post-vaccinal wound infection, although the majority are probably due to this cause; cases have occurred in which the evidence goes far to prove that the erysipelas has been invaccinated. I have discussed these questions (including the alleged transmission of tubercle, leprosy, lupus, &c., by vaccination) at length in the forthcoming volume of Allbutt's System of Medicine, to which I would refer those of your readers who may be interested in the subject.

I am, Sirs, yours faithfully,
THEODORE DYKE ACLAND.

March 22nd, 1897.

"THE COMPENSATORY MECHANISMS OF THE HEART."

To the Editors of THE LANCET.

SIRS,—Dr. Starling, in the first of the Arris and Gale Lectures, reported in THE LANCET of Feb. 27th, made the following statement, which seems to me incorrect in almost every particular: "If the aortic pressure is maintained at its normal height it is evident that in mitral stenosis the work done by the left ventricle must be increased above its ordinary amount, since a certain fraction of the work is wasted in driving blood back into the auricles. Hence, the result of mitral incompetence is, first, increased diastolic dilatation of the left auricle and left ventricle, which later becomes more or less permanent; and, secondly, hypertrophy of the muscular walls of both these cavities." All the books I have on the subject tell me that in typical mitral stenosis cases the left ventricle is *not* hypertrophied. Statistics I have published[1] indicate also that in these cases dilatation of the left auricle is *not* common, except towards the end, when compensation breaks down. Dilatation of the left ventricle is also rare. When mitral stenosis is well developed it is exceedingly improbable that the ventricle wastes its energies in driving back blood into the auricle. A systolic murmur is commonly absent, and I have indicated[2] why, even when the mitral valve is incompetent, regurgitation should not occur. It would contribute to clearness and accuracy if the word "incompetent" were not employed as synonymous with regurgitation, since a stenosed and incompetent mitral orifice is not an orifice at which regurgitation occurs to any appreciable extent. When, however, late in the history of the malady compensation breaks down and the auricle dilates, then regurgitation appears, a systolic murmur is introduced, and cardiac symptoms first become pressing. A second cause of confusion in discussing the physics and the pathology of mitral stenosis arises from not discriminating between slight and severe stenosis. Thus it is incorrect to say that hypertrophy of the left auricle is a characteristic change in mitral stenosis if the stenosis be slight, and correct if it be severe. It is surely important to take notice of such distinctions.

I am, Sirs, yours faithfully,
D. W. SAMWAYS.

Mentone, France, March 19th, 1897.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 20th Dr. Silk raises the question of the frequency of pneumonia in present-day aseptic surgery. I venture in this connexion to quote the following case which has occurred within the last few days at the New Hospital for Women.

The patient, aged twenty-five years, convalescent from syphilis of an aggravated form, was re-admitted on March 11th, after a fortnight's absence from hospital at a convalescent home, for operation the following day, with normal pulse, temperature, and respirations. On the 12th she was anæsthetised by Mrs. Keith, anæsthetist to the hospital, with gas and ether, for removal of hypertrophied labia. The operation was performed with the usual minute antiseptic precautions and lasted half an hour. The temperature rose the same evening to 103° F. and the urine was highly albuminous. By the 15th there was consolidation of the whole lower lobe of the right lung with rusty sputum, and two days later the left lung was attacked. *At the present time the patient is recovering.* She had undergone two previous operations for recto-vaginal fistula and had suffered in no way from the anæsthetic. The inhaler used at the New Hospital for Women has a celluloid facepiece, which is washed before use. It may be mentioned that two other patients had been anæsthetised before this one on the same morning, neither of whom showed any ill after effects. I would suggest that it is to the surgeons we must look for reports of these cases rather than to the anæsthetists, who seldom see the patient after the operation.

I am, Sirs, yours faithfully,
FLORENCE NIGHTINGALE BOYD,
Surgeon to the New Hospital for Women.

Harley-street, W., March 20th, 1897.

THE CELEBRATION OF THE LONGEST REIGN.

To the Editors of THE LANCET.

SIRS,—You published a note from me in THE LANCET of June 4th, 1887, making a suggestion that medical students in London should take part in the celebration of the Queen's Jubilee. Though the scheme was very favourably received by the students of that time, for many reasons the scheme was dropped. Now, although far away from the scene of action, I throw out the suggestion once more. I suggested a torch-light procession, but if any more suitable scheme was brought forward I have no doubt my idea would be passed over. But, Sirs, on this occasion there is much more to be said for the medical students to be represented in the demonstrations of loyalty to the Crown and admiration for Her Majesty. Throughout the British Empire, after the kindly expressions of the Queen and the Prince of Wales, it is extremely probable that medical interests—hospitals, nursing, &c.—will be furthered and established on a more secure and lasting basis; therefore it would be ungracious for the rising medical practitioners not to celebrate the event. Looking forward to the memorable occasion,

I remain, yours faithfully,
A. MARIUS WILSON, M.D. Durh.

Capetown, March 7th, 1897.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—Mr. Thistle asks how hereditary character can originate except by the influence of the environment; he appears, in fact, to think that all new characters are necessarily acquisitions—that they are impressed upon the organism after it has started on its vital career. Mr. Thistle overlooks an important source of new characters—i.e., sexual reproduction. This necessitates a double parentage; and the two parents being unlike the offspring are not exactly like one or the other, there is a mixture of hereditary tendencies which results in the development in the offspring of new characters. The offspring of a single parent are said to be exactly alike—i.e., natural variations are not found among them. Hence Weismann believes that the great purpose of sexual reproduction is to afford variations on which "natural selection" may operate. Now, Sirs, special disease tendencies (the tendency to epilepsy and insanity, for instance) are natural variations, and I see no reason why they should not originate, as strictly physiological variations may do, in sexual reproduction.

In regard to the inheritability of mutilation, we shall be wise to accept the dictum of so eminent a biologist as Professor Ray Lankester—namely, that there is no evidence of it. All supposed instances to the contrary have, as he tells us, broken down upon careful examination. Circumcision carried on for many centuries among the Jews has produced no inherited effect, nor has the docking of horses. Hereditary baldness suggests the wearing of hats by successive generations as its cause. A man does not, however, become bald because his forefathers have worn hard-rimmed hats, but because he inherits a scalp which is very susceptible to the strangulating influence on the scalp-vessels of a hard rim. Men with fine hair go bald, those with coarse hair do not, and these peculiarities are manifestly independent of ancestral custom in the matter of headgear. It is not even certain that the proclivity to such a disease as gout is the result of ancestral indulgences. A man may be prone to gout even though none of his ancestors have led a gout-inducing life. The proclivity to this disease may result from a condition of tissue which is perfectly normal in itself, but one which renders the organism incapable of working healthily under a specific environment. Similarly the inherited incapacity to resist the tubercle bacillus may arise quite independently of any ancestor having been exposed to the conditions which induce tuberculosis. A negro whose ancestors for hundreds of generations may not have suffered from this disease shows a strong tendency to it when he comes to Europe. Here the inherited proneness (for in this case the proneness is inherited) is manifestly independent of a pathogenic ancestral environment, and it is possible that this line of argument applies to most, if not all, diseases which run in families. I quite agree with Dr. Adam's observations.

I am, Sirs, yours faithfully,

HARRY CAMPBELL.

Devonshire-street, W., March 21st, 1897.

"THE PHYSIOLOGY OF THE VESICULÆ SEMINALES."

To the Editors of THE LANCET.

SIRS,—If I read aright Professor Campbell Black's letter under the above title in THE LANCET of March 13th it would appear that his sole objection to accepting John Hunter's and Mr. Heath's views as to the prostatic origin of the urethral discharges voided at stool with the last drops of urine is that some examinations, microscopical and chemical, made by him of urine have enabled him to demonstrate the existence of a certain number of spermatozoa. In the hope that it may perhaps be of service in determining the exact pathological significance of the symptom under discussion, may I venture to suggest that when next a case of this nature presents itself less attention be directed to the clinical examination of the urine and more given to a physical examination of the patient, not omitting a *rectal* examination. Any such examination would have demonstrated to his own satisfaction that these discharges are prostatic in origin, as a little gentle pressure on the prostate with the examining digit will result in the ejectment of the fluid alluded to. It would also have satisfied him that the pathological condition present was an enlarged and irritable prostate. That the fluid so ejected does contain spermatozoa I am not prepared either to affirm or deny. It is not improbable that a few may be found in it, yet, if "a few swallows do not make a spring," it is equally as evident that the presence of a small number of spermatozoa does not *per se* constitute it seminal fluid, especially when we remember that spermatozoa are capable by their own inherent vitality of finding their way from the vagina through the uterus into the Fallopian tubes. I am afraid that I must agree to differ from him as to the existence of unscrupulous quacks within the profession and also that the bulk of patients with these symptoms are "multitudes of young men." For my own part I think that men well past the middle age constitute the great majority. The few young men who come complaining of these discharges are cases in which hypertrophic enlargement of the prostate has been brought about by excessive venery or self abuse. I do not consider that these cases come at all under the head of spermatorrhœa. I fail also to see any analogy between seminal discharges and menstruation, or between "spermatorrhœa" and "menorrhagia." Although the excessive discharge of semen in spermatorrhœa and of catamenial fluid in menorrhagia are both prejudicial to health and of undoubted gravity, yet here the analogy ceases. For in menorrhagia we have an increase in the amount lost at each menstrual epoch, but no increase in the frequency of such periods, while in spermatorrhœa the reverse is noticed. May I venture to question the association of ideas which leads Professor Campbell Black to postulate: "In this case a nerve impulse is conveyed to the brain from the engorged vesiculæ seminales"? I have yet to learn how distension of a hollow viscus *per se* can bring about an expulsion of its contents. I am afraid that any analogy instituted between the vesiculæ seminales and the gall-bladder or urinary bladder will not bear out his assertion. The presence of food in the duodenum originates the nerve impulses that influence the contraction of the gall-bladder on its contents. The irritation of the sensory nerve terminals around the neck of the urinary bladder starts the nerve impulses which lead on to micturition. I must confess my ignorance of the distribution of any sensory nerve fibres passing to the vesiculæ seminales, and trust Professor Campbell Black will demonstrate their existence. I believe the idea popularly accepted will bear me out when I place the centre for controlling the discharge of semen in the spinal cord close to the centres of defecation and micturition. Afferent nerve impulses are conveyed to this centre from the brain under the influence of mental emotions—as fright or lascivious ideas and sights; but the more general origin of seminal ejaculations arises from irritation in the neighbourhood of the glans penis, the urethra, or the prostate. Irritation of the glans penis takes place in coitus; by the retention of secretions under the prepuce, as in phimosis; in balanitis, and sometimes by thread-worms. Urethral irritation is due to the presence of acrid acid discharges, as in sufferers from gonorrhœa, gleet, lithuria, and diabetes, or due to urethral ulcers, polypi, or irritable strictures. The prostate is irritated by a loaded condition of the bowels, by thread-worms, by piles, by stones in the bladder. These are the usual afferent nerve impulses which lead to seminal discharges and serve to explain those cases of night losses where no mental picture arises and where perception of results is deferred till the morning. With apologies for the length of my letter,

I remain, Sirs, yours faithfully,

Rochester, March 15th, 1897. CLARENCE A. WRIGHT.

A MEDICAL SKIAGRAPH SOCIETY.

To the Editors of THE LANCET.

SIRS,—It has been decided to form a Skiagraphical Medical Society. A preliminary meeting with that purpose in view took place on Thursday last at 20, King William-street, London, when the chair was taken by Mr. Sydney Rowland. Among those who are actively supporting the movement are Dr. Macintyre (Glasgow), Mr. C. W. Mansell Moullin, Dr. Low, and Dr. Norris Wolfenden. Any gentlemen wishing to join will oblige by communicating with me.

I am, Sirs, yours truly,

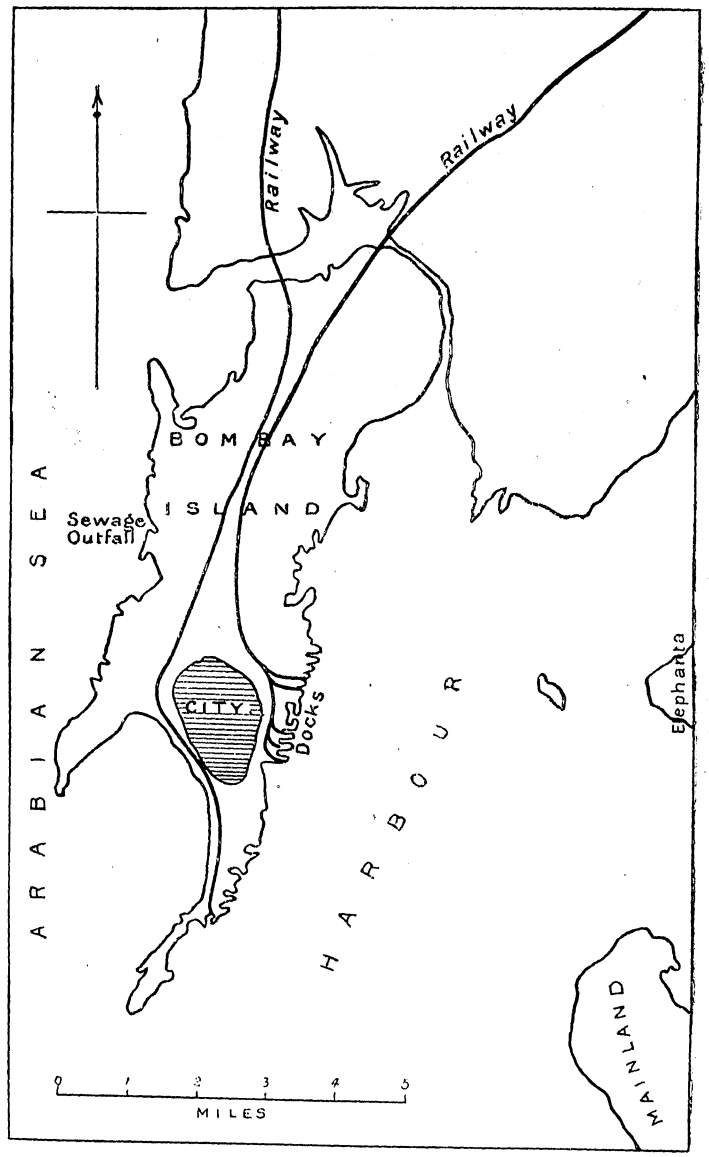
DAVID WALSH, M.D. Edin., Hon. Sec.,

5, Pump-court, Temple, London, E.C., March 22nd, 1897.

P.S.—A meeting of the proposed society will take place at 5 P.M. on Friday next, April 2nd, at the offices of the Medical Defence Union, 20, King William-street, Strand, W.C.

Hosted by Google

THE PLAGUE IN BOMBAY.



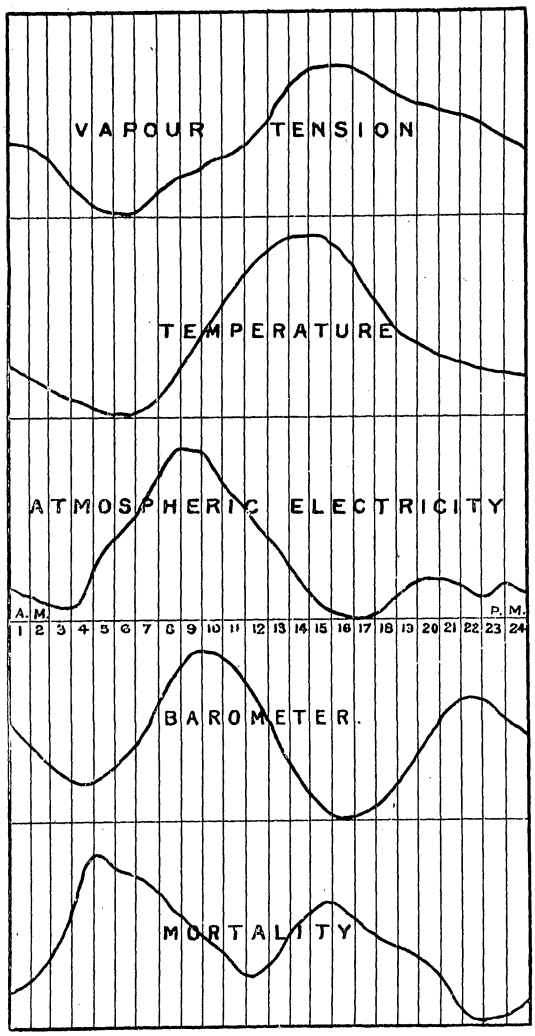
(FROM A CORRESPONDENT.)

THE Island of Bombay lies nearly north and south off the the west coast of India, in lat. 19·0° N. and long. 72 52° E. (See Fig. 1.) The situation and climate are tropical, and its peculiarities will probably be found to offer some special, if not novel, points for study in connexion with the present epidemic of bubonic plague or fever which has not yet been clearly associated with any special and prominent temporary phenomenon that might be regarded as a first cause. The city lies on the southern half of the island, the northern part being occupied by small villages, palm groves, marshes, and cultivated land. The cotton mills are mostly in this part. The southern extremity, Colaba, is a fortified military station. The population within municipal limits in 1891 consisted of 821,000 persons of mixed races, Hindus and Mohammedans predominating. The sewerage system was established some years ago, re-produced from English models at a time when the science of the subject was very little known in India. A considerable portion of the island is below high-water level, and the sewers had to be laid at such levels as necessitated a pumping station at the outfall discharging into the sea at Worlee, on the western side. Enormous deposits of silt accumulated in the sewers owing to an insufficient velocity of current, and the putrefying of this silt and of the sewage flowing over it has distinguished Bombay sewage throughout its course and at the outfall as the foulest in the world. The discharge of sulphuretted hydrogen at the outfall is very excessive and the mortar joints in the culvert are encrusted with decomposing sulphur compounds. The foulness of the sewers may be attributed in great measure to the temperature of the ground and the water of the district. The mean annual temperature of the air in Bombay is 79·13° F., or 30° above that of London, so decomposition of organic matter takes place with a rapidity quite unknown in temperate climates; and if waste matter were removed in Bombay with the same promptitude as is observed in London the smells would still be much more offensive there than here. Solid refuse, such as street sweepings, stable litter, and domestic refuse, are carted away, the sullage and nightsoil being consigned to the sewers—the latter in a manner peculiar to India.

The mean maximum monthly temperature of the ground at 11 ft. below the surface is 84·9°, and the mean minimum 80·9°. The monthly mean range is thus 4° at this depth. The lowest reading of temperature of sewage in the main sewer was 75·7° in the month of February. In England the temperature of sewage in the sewers is generally below 55°. This difference accounts to a great extent for the absence of offensive smells in English main sewers. The average velocity of the wind across Bombay is over twelve miles an hour. This average includes a considerable period of very light winds, but in frequency 72·78 per cent. of them have a westerly component. The island, which has an average width of only two miles, should be very well ventilated and healthy under the influence of the winds were it not that the city was built before the existence of municipal influences. Many of the streets are therefore very narrow and crooked, and houses in these quarters have been built up to six storeys in height. In these districts or wards the houses cover as much as 85 per cent. of the ground area, and the density of population reaches 760 per acre, a figure unequalled anywhere else in the world. Generally speaking, the greatest density of population in London is less than that of any out of twelve sections of Bombay, which average 458 persons per acre.

During the five months of rain the people have to sleep under shelter, but the temperature of this period is generally above 80°, with a diurnal range which at times does not exceed 2°. Very little covering is therefore needed at night. But as there is absolutely no control over the crowding in dwellings the limit of accommodation is fixed by the number that can get in. As many as eight coolies will sleep in a room ten feet square and eight feet high, with both door and window shutter closed. There is no chimney in such rooms, and the cubic space per man is just one hundred feet, or one-sixth of that prescribed by de Chaumont. During the present month the nights have been unusually cold, the temperature out of doors having fallen to 64°. This has driven people indoors, and has caused a rapid rise of mortality. Going out from the warm and very foul atmosphere of a room, where they have been huddled together during the night, the half clothed coolies fall easy victims to the raw air of the early morning which is still contaminated by the exhalations from the ground. It has, of course, been known for a long time that overcrowding is everywhere inimical to good health, but no active measures have been taken in India to prevent it, except in camps and barracks.

FIG. 1.



Corrected chart of the island.

Any interference on the part of public bodies with the habits of the people would be taken, at least at first, in the worst spirit, and it is now evident that interference to a very important extent must take place in order to obtain a reasonable measure of security for public health. In addition to the fixed population of Bombay, there is a constant circulation of strangers of the labouring class who come for months or years from the mainland to enjoy the better pay and the excitements of a large city. These people supply much of the skilled and unskilled labour of Bombay, and they provide most of the domestic servants and office messengers. Their habits are of the most primitive kind, they ignore every sanitary precaution, the street is their latrine, and at night they will throw nightsoil out of the windows into streets and lanes if they cannot find within doors a sink to suit their purpose. They live in the offices in the Fort without any proper quarters, and Elphinstone Circle, the best business part of the Fort, has been rendered unwholesome by the filth, office sweepings, and other rubbish which they throw into neglected courtyards and alleys. All Indian domestic servants have the same habits, formed in the jungle and acquired or inherited by the poorer classes, and they rarely receive any training in sanitary habits from their employers. There is thus a large section of the population whose lives are a constant violation of all sanitary rules and whose habits render them a constant element of danger. Their filthy habits have greatly increased the cost of conservancy in Bombay. Every appliance devised for their convenience has been abused and damaged. Public and private latrines have been damaged or filled with stones and other solid matter, and the gratings of public urinals were promptly stolen and sold or used as fireplaces. Down-take sullage pipes with their syphons are constantly filled with sand, leaves, rags, and other refuse, so that a large staff of men are constantly employed in clearing them at the expense of the city.

During the seven months of interval between the monsoons the sullage and other refuse thrown out of doors gradually foul the surface of the ground for some distance downwards. This continues to increase until the next monsoon cleanses the ground. If the rains begin with showers alternating with sunshine the wet, impure ground is heated, and a prompt increase of mortality is observed. No systematic analysis of the air of Bombay has yet been made, although there is reason to believe that the health of the city is influenced to a considerable degree by its smell. Inspectors of the Health Department had observed that foul smells were most apparent about houses at 4 A.M. and 4 P.M. long before they knew that these were the daily periods of low barometric pressure. It occurred to the writer eight years ago to inquire into the correspondence between the mortality during the day and night, hour by hour, with the movement of the barometer. The result is shown in the accompanying table of daily phenomena (See Fig. 2.) The four upper curves are the means of at least twenty years' observations at the Observatory, Bombay, and the mortality curve was obtained from the registers of

FIG. 2.

Curves of natural phenomena showing the relation of the daily mortality to the meteorological changes.

FIG. 3.

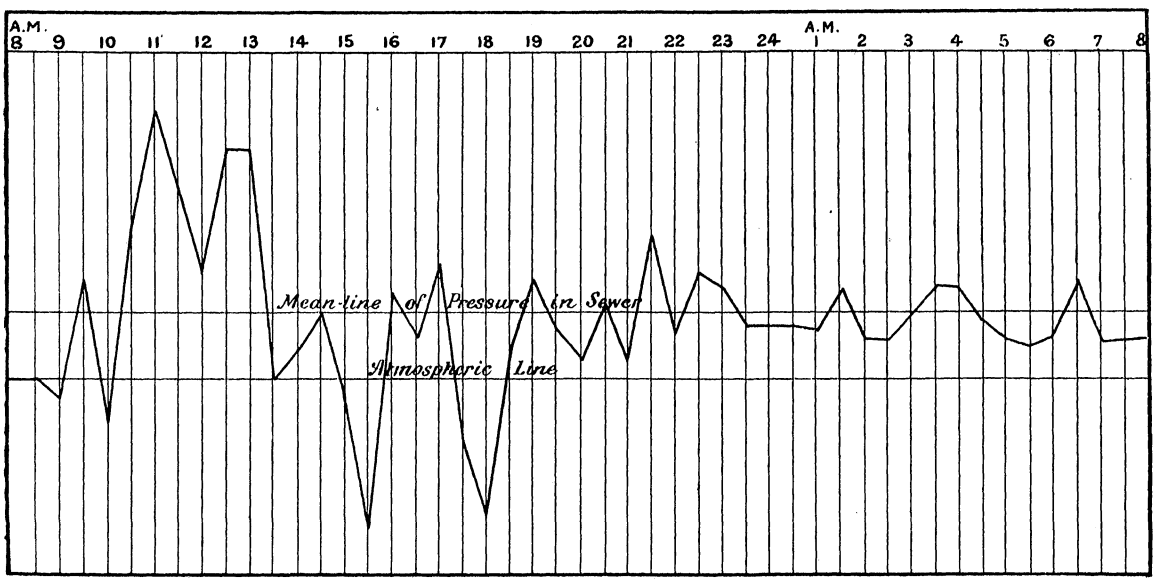

Diagram of changes of pressure in the sewer atmosphere in Bombay. This pressure was equal at 11.0 A.M. to a theoretical escaping velocity of six miles per hour.

Hosted by Google

deaths at the Jamsetjee Jejeebhoy Hospital, Bombay, extending over four years. All violent deaths were eliminated before the certificates of death were classed, and all the curves were reduced to a uniform height in preparing the diagram, so that correspondence might be the more easily observed.

The low barometer at 4 A.M. is quickly followed by the highest mortality in the day. This mortality falls until noon, and rises until within half an hour of the afternoon low pressure. Ten at night is the period of least mortality. Although the afternoon pressure is lower than that of the morning, the influences of sunlight, convection from the warm ground, and of the sea breeze all tend to purify and dilute the escaping ground air, whereas in the morning the low vapour tension and steadily falling temperature keep the impure air as it issues from the earth near the surface until sunrise, when convection begins. The early morning is usually a period of calm, and as the impure ground air is at equal temperature heavier than pure air it tends to lie until the sun rises. The low mortality at 10 P.M. appears to be due to the combined action of sea breeze, sunlight, and the temperature of the ground aided by a rising barometer. It is to be regretted that no corresponding observations have been made in other large Indian hospitals. The strength and frequency of sewer smells in Bombay led the writer to make a twenty-fours hours' experiment on the main sewer to note the fluctuations of pressure in half-hourly observations. The gauge, reading accurately in thousandths of an inch of water, was placed in a closed building and coupled on to a recess in the sewer. There was only half an hour of normal pressure (from 8 to 8 30 A.M.). At 11 A.M. the pressure was equal to a theoretical escaping velocity of 6·07 miles per hour. At 3 30 P.M. there was a minus pressure equal to a velocity of 4 59 miles per hour, and the mean of the forty-eight readings represented a theoretical escaping velocity of 3·01 miles per hour. (See Fig. 3.) This experiment indicates very imperfect ventilation. The ventilators mostly in use consist of a double tube with the heads bent and pointing in opposite directions. It had been assumed that the wind acting on either mouth would displace a cubic foot of foul air from the leeward mouth for every cubic foot of pure air injected by the windward mouth. The application of the gauge showed that the direct current was much stronger than the induced one, and that the action of the wind on the ventilators, instead of relieving pressure in the sewer, actually increased it, and increased the escapes at the ground level.

This experiment seems to be the only one that has so far been made on pressure in the sewers, although extended observations are needed to give a true basis for adequate ventilation, but it has sufficed to show in a most emphatic manner the unsuitability of a system of drainage copied from a foreign model in which the element of underground temperature could with safety be ignored. The whole interior surface of the Bombay sewers is covered with putrid matter which acts as a ferment on all the sewage that enters. The change of pressure in the sewers does not correspond with the barometric curve, but varies with the volume of liquid passing through them. If the rate of current in all the Bombay sewers could be made self-cleansing there would be a great diminution of the gases of decomposition, arising principally from the mud which accumulates on the invert, and which is at present moved along by means of an appliance drawn by a crab winch and a chain which passes through manholes. The rate of movement of the silt by this means is only three and four-tenth miles a year, and the agitation of the process promotes an active discharge of gas of the foulest kind, which escapes through the open manholes. Adequate ventilation would disperse these gases above the roofs of the houses, but as they seem to be inseparable from the existing system of masonry sewers many sanitary engineers in India already believe that cast-iron pipes are the only suitable material in which sewage may be safely transported in the tropics, and that the velocity of the current should be so controlled by pumping that no deposit could lie in the pipes. This opinion gains weight when considered in connexion with sewage irrigation which is already in successful operation in Madras and Karachi. Sewage which is pumped to the outfall can be discharged within a fixed time from the period of entering the sewer, a most important consideration in the tropics.

The habits of the people at large render domestic privies attached to the sewers a practical impossibility. They will not flush them, and they persist in blocking them with solid matter. It is for this reason that in a city possessing sewers the greater part of the nightsoil is collected from house to house by men belonging to the lowest castes, and carried on their heads in waterproofed baskets to depôts where it is discharged into the sewers. Each load of about thirty-five pounds is carried an average of one and a half miles, making in all three miles of walking per load. The smell arising from these depôts is most offensive, and for this reason they can only be established in open spaces. Any attempt to multiply them would be met by the strongest opposition from the people. A small model depôt was tried, in which a basin about twenty-seven inches in diameter could receive the nightsoil of 6000 inhabitants. The baskets or pails were washed automatically in a few seconds by upward and downward jets of water; but the difficulty of locating them seems to have stood in the way of adopting a number of depôts of this kind. The *halalcores* who perform the work of removal appear to be proof against attacks of plague. Had they fled like the other Hindus the city would have been in a worse plight than in 1893, when on Friday, Aug. 11th, the Mohammedans attacked the Hindus on a question of religion and began to murder them promiscuously. On the following day, Saturday, the Hindus, recruited from the cotton mills, took the initiative to avenge their friends. Shops were closed, business was suspended, the sick were neglected and the dead unburied, while the thermometer ranged from 77° to 83° F. The *halalcores* dared not work, and filth of all kinds accumulated to a frightful extent before order was restored by the rifles of the garrison. The *halalcore* work had meanwhile been suspended in the native parts of the town, including the markets, for nearly eighty hours.

It will thus be evident that the sanitation and conservancy of a large and greatly over-populated oriental city present features and difficulties that are unknown in colder and more civilised countries.

It is doubtful if segregation could have been effectively applied by means of any cordon at Bombay to prevent the escape of the people inland. A city so densely overpopulated as Bombay is would require an enormous increase of house accommodation to lodge the people who from necessity or fear have left their dwellings and gone into the interior or to other coast towns. The huts that have been temporarily constructed in various parts of Bombay for public or for special use are avoided by the poorer classes, for whom they were made, for reasons which are now becoming apparent. As previously stated, the native in cold weather shuts himself up in his sleeping room, and obtains warmth not by extra coverings but by overcrowding. He has very little bedding, and if he has a bed raised from the floor his scanty coverings render him all the more sensitive to a fall of temperature. At this season dry, cool winds from the north-east prevail, alternating with the moist, warm sea breeze, and the land wind which now blows every night produces colds and fevers among those exposed to it. Bamboo and mat huts, although superior to tents in warm weather, are only comfortable at present in the night for those who are sufficiently protected with clothing or bedding. This is noticeable at the Arthur-road Fever Hospital provided by the Bombay Municipality for plague cases, and which has at present about ninety cases with accommodation for 100. The cool, dry air, acting on skins accustomed to a moist, warm atmosphere has had fatal effects on many of the patients. This hospital, which is in the charge of Dr. Choksey, one of the most capable and devoted of the Parsee medical practitioners, has suffered since it was opened from dearth of assistance. Nurses and ward boys have been lacking, to the prejudice of the work. This defect is now being remedied. Some of the other hospitals are having special fever wards attached. The Parsee community is the only one which has established a plague hospital of its own, which, at present, contains thirty cases, one half of which are convalescent. This hospital is due to the initiative of Dr. K. N. Bahadhurji, and is under his direction. A roomy and well ventilated bungalow was secured in a northern suburb with open space all round it, and nothing seems to have been forgotten that could conduce to the comfort of the patients or the good management of the hospital. Light screens separate the patients, giving them a sense of privacy without isolation, ample ventilation is ensured with protection from draughts, and the most scrupulous cleanliness is maintained throughout the premises. It is to be hoped that this hospital will do much in overcoming the prejudice against hospitals which is at present so common among all classes in India.

We seem to be still a long way from any reliable theory of

Hosted by Google

the bubonic plague. It is still uncertain whether the bacillus associated with the malady is a cause or an accompaniment, and this disease, so popularly ascribed to filthy surroundings, has recently broken out severely in the Bombay House of Correction, which is generally regarded as a model of cleanliness and good management. M. Haffkine has inoculated those of the prisoners who responded to his invitation to submit to the operation, but no satisfactory explanation has so far been found for the outbreak. The research of Dr. Bitter will, no doubt, be as thorough as time and circumstance will permit; but the absence of systematic observation of the air and soil in the city will probably deprive him of data that should greatly assist his inquiry into bubonic plague.

Bombay, Feb. 5th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE 117th annual meeting of this hospital was held on March 17th under the presidency of the Lord Mayor (Mr. James Smith). The report stated that the income for the year was £14,198 3*s.* 3*d.*, the expenditure £17,884 5*s.*, this being £1223 8*s.* 4*d.* more than that of the previous year. The average cost of each in-patient was £2 16*s.* 6*d.*, against £2 11*s.* 1*d.* in 1895. The number of in-patients was 4486, of out-patients 52,203, being an increase of 25 in-patients and a decrease of 405 out-patients. Of the in-patients admitted 859 were children under twelve years of age. There was an increase in the number of serious operations during the year, there being 1090 against 1055 the preceding year. The Lord Mayor called attention to the fact that this annual meeting would be the last one in the present building: he alluded to the history of the building, and to the vast amount of good done since its foundation by Dr. Ash in 1766. During that time there had been on the staff twenty-four physicians and twenty surgeons. The adoption of the report was seconded by the chairman of the committee, who paid a fitting and graceful tribute to the memory of Mr. Oliver Pemberton.

The Ear and Throat Hospital.

The governors and subscribers held the fifty-second annual meeting on March 18th, the Lord Mayor presiding in the absence of Lord Leigh. The total number of out-patients registered for the year was shown to be 6059, being 352 more than the previous year. In-patients to the number of 373 were admitted. The registration fees paid by patients amounted to £431 18*s.* The expenditure has exceeded the income by £111 15*s.* Mr. Wilders, who had acted as surgeon to the institution for over thirty years, was elected upon the honorary staff, and Lord Leigh was re-elected as president.

The Dental Hospital.

The Lord Mayor also presided at the thirty-seventh annual meeting of this hospital on March 5th when the report was stated to be the most successful one the charity had yet presented. The total number of operations performed during the year was 22,596. The financial statement showed that the income from all sources amounted to £934 9*s.* 7*d.* and the expenditure to £705 1*s.*, leaving a favourable balance of £229 8*s.* 7*d.* Mr. Sims, dental surgeon, pointed out that the hospital was established for the benefit of the poor, but it was becoming more a dental school than a hospital. He protested against much of the gratuitous work done at the institution, and said that many went to the hospital who could afford to pay; only last week three patients who had gone to the hospital to have their teeth extracted had afterwards come to him as a qualified dental surgeon for artificial teeth. He added that one-third of the patients who attended the hospital ought not to go there at all. These statements, it is hoped, will receive the attention of the committee.

The Medical Institute.

The report of the Medical Institute for 1896 has just been issued. It states that after twenty years of existence the number of members is 196, the income is £440 2*s.* 8*d.*, and the number of books in the library 12,088. The number of members is less than it was ten years ago, and the financial position is unsatisfactory, the balance-sheet showing a deficit of £71 11*s.* 8*d.* The report further points out that a large number of practitioners in the district are not members and expresses regret that the many advantages of the institution do not seem to be sufficiently appreciated. At the annual meeting, held on the 18th inst., Dr. Saundby was re-elected president, and the debt was stated to have been wiped out by a few generous friends.

Funeral of Mr. Oliver Pemberton.

On March 11th in the quiet churchyard of Shustoke the remains of Mr. Pemberton were deposited with simple, but impressive, ceremony. A large number of representative citizens of Birmingham, including the Lord Mayor, attended by special train, together with many professional men, friends of the deceased. The service at the grave was conducted by the Rev. W. H. Poolton, Warden of Queen's College, one of the coroner's oldest friends. Many votes of condolence with the family have been passed by various public bodies with which Mr. Pemberton was connected, and on all sides much sympathy has been expressed, the depth of which has been emphasised by the death, a few days later, of Mrs. Pemberton, as noted in THE LANCET of March 20th.

The Jubilee Commemoration.

An influential public meeting was held on the 22nd inst. to establish a fund fort his purpose. The scheme includes especial attention to the wants of the sick and suffering poor, in accordance with the wishes expressed by Her Majesty the Queen. A sum will be provided for increasing the work of the District Nursing Society, to endow beds at the General Hospital, Queen's Hospital, and Children's Hospital, and in other ways to promote the permanent record of so auspicious an occasion.

March 24th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary.

THE reports of the medical, surgical, and pathological registrars, just issued as a small octavo volume, neatly bound in cloth, are a new feature in the annals of the Royal Infirmary. Towards the end of the year 1895 a small committee was formed to superintend the issuing of a medical, surgical, and pathological report. The present report, although comparatively small, will, it is hoped, be found accurate and of use to the investigator and the student. The statistical tables have been drawn up with every care, and as many data as possible have been inserted to make them complete. The pathological report gives a short *résumé* of each necropsy, and brief commentaries are made upon the more important cases. The medical statistics include general diseases; effects of poisons; malingering; nervous system, comprising (*a*) nerves, (*b*) spinal cord and membranes, (*c*) brain and membranes, and (*d*) functional; diseases of the circulatory system; respiratory system; digestive; urinary; ductless glands; locomotory system; integumentary; diseases due to parasites; eyes; ears; nose and naso-pharynx; and diseases of the female generative organs. The total number of medical cases recorded amount to 1122, of which 631 were males and 491 were females, with ages varying from five to sixty years and upwards. The results of treatment represent 348 as cured, 488 relieved, 107 unrelieved, 27 transferred, and 152 died. The surgical statistics deal with every variety of lesion, immediate and remote; diseases of joints, injuries and diseases of the head, spine, and nerves engaging considerable attention. Of the major operations performed in the gynæcological wards, of which there were 113, there were four amputations of the cervix, 36 cases of perineorrhaphy, 13 posterior sections, 21 laparotomies for various affections (including double ovariotomy, ovarian cysts, hæmatosalpynx, fibro-cystic tumours, dermoid of ovary, epithelial tumour of broad ligament, and ascites), 8 of curetting, 9 of lacerated cervix-plastic operation, besides other operations, from all of which only two patients died, a footnote stating that the deaths were due to intestinal obstruction not connected with the operation. A couple of pages are also devoted to a classification of diseases of in- and out-patients in the gynæcological department. The post-mortem statistics, which include 110 examinations, are full of interest. The reports would be still more complete but for the accidental omission of the statistics of the lock wards, which, no doubt, will be inserted in the next issue.

Hosted by Google

Pathological Department of University College, Liverpool.

In view of the increasing number of specimens of tumours, diphtheritic membranes, and specimens of blood (typhoid fever cases) which are sent to the pathological department for purposes of diagnosis, it is proposed to engage a skilled laboratory assistant who shall devote his whole time to section cutting and bacteriological examinations, under the direction of the Professor of Pathology. Members of the profession upon payment of a small annual subscription will be entitled to: (1) histological examination of all tumours; (2) examination of specimens of blood; (3) examination of urinary deposits; (4) examination of tuberculous and pneumonic sputa; (5) bacteriological examinations of, and supply of, test tubes for diphtheritic membranes, pus, and sputa; and (6) the examination of the blood of suspected cases of typhoid fever, and supply of capillary tubes for same. The Professor of Pathology, Dr. Rubert Boyce, hopes to commence the examinations in May next, if members of the profession will lend their support to the scheme by becoming subscribers.

Admissions of Lunatics to the Liverpool Workhouse.

The admissions to the lunatic wards of the Liverpool Workhouse for the last three months do not bear out the statements that lunacy is everywhere largely on the increase, inasmuch as fewer cases have been certified for removal to that institution than during the corresponding periods of the last seven years.

Health of Liverpool.

The medical officer (Dr. Hope) reports that the births registered in the city during the week numbered 474 and the deaths 285, a death-rate of 23 per 1000 per annum. Of the deaths 70 occurred in public hospitals, and 98 were those of children below five years of age. Lung diseases occasioned 71 deaths; tuberculosis, 35; brain diseases, 35; heart diseases, 24; and zymotic diseases, 34. 118 infectious cases were notified and 44 discovered by officers of the committee; 361 patients were in the city hospitals, against 349 the preceding week. The mean temperature for the week was 40·6° F.

March 23rd.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The University College of South Wales and Monmouthshire.

A MEETING of the council of this College was held in Cardiff on March 17th, under the presidency of Dr. Price. A letter was received from Messrs. Samuel Brothers of Cardiff enclosing a cheque for £500 for the founding of a medical scholarship at the College. The donors were desirous of making the gift as a recognition of the benefits enjoyed by the Jewish community during the sixty years of the Queen's reign. A cheque for £169 was received from the town and working men of Pontypridd as a further contribution towards the building fund of the College. The council then considered applications for the post of Professor of Anatomy, and resolved to invite Mr. Dickson of Trinity College, Dublin; Professor Fawcett of University College, Bristol; and Mr. Manners Smith of Mason College, Birmingham.

The Proposed Convalescent Home for Bristol.

The Mayor of Bristol issued last week an appeal to the citizens of Bristol for funds towards the proposed convalescent home. He states that the committees of the infirmary and hospital urge the need of the home, and it has been proposed that, without charge to them, sixty beds should be reserved for their patients, and that twenty beds should be retained for other cases that will be admitted on such terms as will be ultimately decided upon. Thus it is estimated that annually 1000 of the infirmary and hospital patients and about 350 others will materially benefit by such an establishment. For the building, equipment, and endowment of the home at least £50,000 will be required. Several subscriptions have been promised, and Mr. E. P. Wills has offered £10,000 on condition that a further £50,000 is raised, and an additional £3000 should the fund reach £97,000. Mr. H. O. Wills has given £10,000, and the total contributions by members of this family, assuming the scheme is completed, will be over £25,000.

The Notification of Infectious Diseases at Bristol.

At a meeting of the Bristol Town Council, held on March 9th, it was resolved that the port sanitary authority should adopt the Infectious Diseases Notification Act, to apply to yellow fever, plague, and measles, in addition to the diseases specifically mentioned in the Act.

The Literary and Philosophic Club, Clifton.

Last week, at Clifton, Professor Lloyd Morgan, the Principal of University College, Bristol, gave the second of his two lectures in connexion with the Literary and Philosophic Club, Clifton, entitled "Habit and Instinct." The lecture was most interesting and gave many details showing how far creatures act from instinct and how far from acquired knowledge and experience. Professor Morgan mentioned some of the things noticed when a number of young birds were hatched out in an incubator, and therefore kept entirely free from any parental teaching. He found that most of these young birds instinctively pecked, seized, and swallowed any small object which attracted their attention, but were not guided by instinct in selecting what was good or bad for them.

The Infectious Diseases Notification Act at Bath.

At a recent meeting of the Bath Sanitary Committee the medical officer of health (Dr. W. H. Symons) reported that during the last few months several instances of default under this Act had come to his knowledge. Twice recently he had had complaints from medical officers of health of persons being sent from Bath in an infectious condition, and more often he had found persons coming to Bath in a similar condition. On investigation he generally found ignorance or thoughtlessness to be the cause, and under such circumstances deemed a warning sufficient; but there was one case in which he thought there ought to be a prosecution, and consequently the sanitary committee decided to prosecute.

The Cardiff Guardians and Vaccination.

At the meeting of the Cardiff guardians, held on March 6th, it was decided, upon the recommendation of the vaccination committee, that it should be made a condition of the contracts for public vaccination that vaccinations should be with calf lymph, and that the fee for successful vaccination be increased by 2*d.* in each case to meet the extra cost, which it is estimated would amount to about £40 a year. The committee recommended that the fee should be increased by 3*d.* for each case, but one guardian objected "to the virtual increase of salary proposed, and moved that the fee be increased by 2*d.* only," and this amendment was adopted.

Reduction of a Medical Officer's Salary.

At the last meeting of the Carmarthen board of guardians a letter was read from Mr. W. Lewis Hughes, M.R.C.S. Eng., L.S.A., resigning his appointment as medical officer for the Carmarthen Urban Division owing to ill health. The resignation was accepted, and the board decided to advertise the vacancy and reduce the salary from £80 to £70 per annum.

A New Hospital for Poole.

At a meeting on March 9th, at Poole, the Mayor (Lord Wimborne) explained his recent offer to give, as a commemoration of the Queen's reign, to the borough of Poole a mansion and grounds now known as the Cornelia Hospital and £1000 towards the endowment fund of the hospital. It was resolved to accept Lord Wimborne's gift and to raise an endowment fund. Lady Wimborne has practically maintained the Cornelia Hospital, Poole, for the past eight years, and has just issued the report for 1896. The balance-sheet shows a deficiency of £592, but this has been made up by the generosity of Lady Wimborne.

March 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medico-Chirurgical Society.

A SPECIAL meeting of this society was held last week, at which the plans of the new City Hospital were exhibited by means of limelight, and described by the city architect and the medical officer of health. The chairman of the public health committee of the town council explained at the outset the reasons for the selection of the site for the new hospital, and stated that it was the desire of the committee to

Hosted by Google

carry with them the support of the medical profession. The site of the new hospital was approved of by the meeting, and it was agreed that the number of beds should not be less than 600. This is an interesting and important departure and should not pass without being emphasised. It is doubtful if a public health body has ever before brought its proposals and plans before a meeting of medical men for criticism. The step indicates an enlightenment and liberality which is greatly to the credit of the public health committee and its convener, Baillie Pollard; and it is an example which might be followed with great advantage by many other public health authorities.

Scottish Association for the Medical Education of Women.

The seventh annual meeting of this association and the prize distribution to the students attending its college in Minto House, Edinburgh, were held last week. Sir Alexander Christison presided, and Sir William Muir, Principal of the University, presented the prizes. In the report it was stated that there were now eighty students at the College and that they had begun with nine. Reference was made to the opening of the University degree to women and the recognition of the school by the University.

The Faculty of Advocates and Chalmers's Hospital, Edinburgh.

The Edinburgh Faculty of Advocates has determined to follow the Royal suggestion that Her Majesty's Diamond Jubilee should be characterised by works of beneficence. At a meeting last week it was decided to subscribe money for the extension of Chalmers's Hospital, a hospital of which the Faculty is the governing body.

Changes in the Royal Infirmary, Edinburgh.

Dr. Wyllie's term of office as a physician to the Edinburgh Royal Infirmary will expire at the end of this month. Dr. Bramwell, the senior assistant physician, will become a full physician, and there will be a general move among the assistant physicians. Dr. Gibson will go to the wards devoted to the instruction of women; Dr. Bruce will be attached to Sir T. Grainger Stewart; Dr. Philip to Professor Fraser; and Dr. Russell to Professor Greenfield; the others will retain their former places. Much regret is expressed at Dr. Wyllie's retirement, for he has long been regarded by his colleagues and by the students as one of the greatest personalities in the infirmary.

Glasgow Medical and Chirurgical Society.

This society met on the 19th inst., the President, Dr. W. L. Reid, being in the chair. Dr. D. J. Mackintosh gave a lantern demonstration to illustrate the value of the x rays in hospital practice, more especially as regards dislocations and fractures. The slides exhibited demonstrated: (1) the value of the rays for diagnostic purposes in cases where physical examination was not conclusive; (2) the actual displacements which occur in various classical fractures; a number of slides showing cases of Colles's fracture and Pott's fracture were very successful; and (3) the conditions which exist in ununited and in badly set fractures. Amongst the most striking of the photographs were those illustrating congenital dislocation of the head of the femur, the presence of a coin in the coils of the small intestine low down in the pelvis, and several dealing with various injuries in the region of the elbow-joint. Dr. Mackintosh also illustrated the use of the cinematograph for purposes of medical demonstration. He threw upon the screen a series of rapidly taken photographs of patients suffering from locomotor ataxia, diphtheritic paralysis, and hemiplegia, and as these walked round and round in a circle the peculiarities of the gait in each case were very manifest. Dr. Maitland Ramsay gave a lantern demonstration to illustrate the diseased conditions of the eye due to syphilis. The slides were of great beauty and formed a complete clinical picture of the diseases under consideration. They included chancre of the upper lid, chancre of the lower lid, specific tarsitis, disease of the cornea in acquired syphilis, gumma of the iris, gumma of the ciliary body, and specific choroiditis and retinitis. A number of slides illustrating changes in the eye and in the general physiognomy as a result of inherited syphilis were also exhibited.

Medical Lectures in Glasgow.

At the February meeting of the Microscopical Society Dr. L. R. Sutherland, assistant to the Professor of Pathology at the University, gave a demonstration of the effects of tuberculosis as seen in various parts of the body. The demonstration included a large number of preparations, microscopic slides, and diagrams. In his remarks Dr. Sutherland discussed the nature of tuberculosis, the modes of infection, and the conditions generally which influenced the incidence of the disease. On the motion of Mr. J. Rankin, B.Sc., he was awarded a cordial vote of thanks.—At a recent meeting of the Philosophical Society Dr. John Macintyre gave an account of the more recent advances made in connexion with the x rays. He claimed to have sent the rays sixteen feet across a room, through a partition, and then to have examined with them the contents of a box in the next room. The use of the rays for various purposes were illustrated, including their application as a test to distinguish genuine diamonds and pearls from false ones. Dr. Macintyre also showed the movements of the knee-joint by means of the cinematograph. He expected that before long all the movements of the body would be recorded by means of the photographic film.—The first of a series of lectures to ladies organised by the Total Abstinence Society was delivered in Glasgow by Dr. P. A. Young of Edinburgh on the 16th inst. Dr. Young argued that physiology, experience, and the statistics of life insurance societies were strongly in favour of total abstinence from alcohol in all forms.

Glasgow University.

The close of the session has been succeeded by the onset of the professional examinations, which are continued throughout the whole of the present week. The lists include a considerable number of women candidates.—At a meeting of the members of the Union on the 17th inst. Mr. J. C. Monteith was elected President; Professor Joseph Coats, Vice-president; Mr. F. A. Macquisten, B.L., treasurer; and Mr. Anderson McKendrick, secretary.—The last meeting of the Queen Margaret College Medical Club was occupied by a paper on Student Life in Vienna by Dr. Margaret Dewar.

St. Andrews and Dundee.

The wearisome quarrel between the academic authorities in these two cities appears to be entering on a more dramatic phase. There has always been a minority in the University Court at St. Andrews willing, if not anxious, to come to an arrangement with Dundee so as to secure for the University the advantages which Dundee is able to offer to students of medicine and science. The recent decision of the Privy Council practically upheld the contention of this minority to the effect that by the ordinances framed by the Universities Commissioners Dundee College is an integral part of the University of St. Andrews. But the majority of the Court appear to be resolved to pursue their course heedless of the Privy Council and its decisions. Accordingly the minority have declined to take part in the meetings of the Court, and at a meeting on the 19th inst. Principal Donaldson, on behalf of himself and five other members, including Principal Stewart and Principal Mackay, M.D. Glasg., of Dundee, lodged a written protest against the validity of the proceedings and then withdrew from the meeting. Thereafter the majority proceeded to transact the business of the Court, including the appointment of a Professor of English Literature. However interesting the moves in this academic struggle may be as mere exhibitions of diplomatic ingenuity, there are signs that the public is becoming somewhat disgusted with the performance. It is, indeed, nothing less than a scandal that the management of an important national institution should be conducted in such a way as to prejudice the educational and academic interests of two colleges, each of which in its own sphere is capable of contributing an element of value to the success of the University.

Medical Appointment.

Mr. J. D. Graham, M.B., C.M. Glasg., has been appointed House Surgeon to the Smithston Asylum, Greenock, *vice* Mr. W. S. Cook, B.Sc., M.B., C.M. Glasg., resigned.

March 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Illness of the Archbishop of Dublin

LORD PLUNKET, the Archbishop of Dublin, is seriously ill. He is attended by Sir Francis Cruise, of the Mater

Hosted by Google

Misericordiæ Hospital, and Sir Philip Smyly, of the Meath Hospital.

The Health of Dublin.

The unfortunate coincidence in the city of three different epidemics—namely, scarlet fever, measles, and whooping-cough—has rather overstrained the resources of the public health officials and left them and their department open to much adverse criticism. At the annual meeting of the Dublin Sanitary Association the Registrar-General (Dr. Grimshaw) stated that according to the returns at that precise date "the only place that beat Dublin in the height of its death-rate was Bombay, which had a mortality of 102 per 1000." Mr. Roche also made a strong speech on that occasion, and has ever since been bombarding Sir Charles Cameron with questions. Why are not all the schools in the city closed? Why are not the contents of the pawnbrokers' shops disinfected? Why has not the state of the tenement houses been set right? Why are fifty-six slaughter-houses allowed to exist in the city in addition to the public abattoir belonging to the corporation? On the other hand, the Lord Mayor has recently said in public that the present mortality is largely owing, in his opinion, to poverty and wretchedness among the labouring class in Dublin, brought about by the prolonged building strike of last year. The Dublin Sanitary Association, moreover, should remember that while Sir Charles Cameron and Mr. Stafford, the medical inspector under the Local Government Board, proposed the establishment last year of a special hospital outside the city for the treatment of infectious disease, the project was strongly and effectively opposed by the association. The main drainage works are being pressed forward by the corporation with commendable energy and at an expenditure which will ultimately reach at least £200,000. An inspection has recently been made of all the tenement houses, while the 5000 dairy cows in the city have been examined. Circulars have been sent to all the city schools recommending that they should be closed, the corporation not having any power to close them compulsorily or to inflict the money loss on the teachers which such a measure would entail. Many of the schools have, however, been closed. The private slaughter-houses cannot be closed without a considerable expenditure in the shape of compensation. The whole problem is a difficult one, and at bottom to a large extent a question of money. The city rates have gone up by leaps and bounds and are now over 9*s.* in the pound, and the municipal accounts for 1896, which have just appeared, show that they are likely to become much higher. The cost of the sanitary department rose last year from £20,922 to £23,710; nearly £8000 were added to the cost of the cleansing department, which advanced from £40,000 to £48,000; and the sewer-rate expended in the North and South districts was increased by £5000. These items may be classed as sanitary, and they show in the gross an increase of £13,322, or nearly 20 per cent.

County Antrim Infirmary, Lisburn.

From the annual report I find that 325 patients were treated in hospital during the year ended Nov. 30th, 1896, and 604 in the extern department. There were 211 accidents attended to last year and 72 operations performed. The infirmary has been selected by the Lady Pembroke Committee of the Irish Workhouse Reform Association for the purpose of training nurses for union infirmaries, and a probationer has been sent to be trained at Lady Pembroke's expense. This will be a boon to boards of guardians in Ireland, who by Lady Pembroke's generosity will have trained and educated women of the middle-class as workhouse infirmary nurses.

Belfast Royal Hospital.

At a special meeting of the corporation of the Belfast Royal Hospital held on March 15th it was decided to raise a sum not exceeding £2500 out of the invested funds of the hospital to pay off the present debt. This has been done as it was thought unwise, by making any special effort to raise funds, to interfere with the present scheme for the erection of the new hospital in Belfast, the subscriptions to which amount now to £73,000, including the large sum of £5000 given by Mr. Gallaher.

The Proposed New Fever Hospital.

A memorial signed by over 100 members of the medical profession practising in Belfast objecting to the site at Purdysburn for the new Fever Hospital is about to be presented to the Lord Mayor and city council. In this memorial, which has been drawn up by a sub-committee appointed by the councils of the Ulster Medical Society and of the North of Ireland Branch of the British Medical Association, the objections which exist to the proposal to erect the new hospital for infectious diseases at Purdysburn are thus stated: (*a*) the distance is too great (two to eight miles) for the transference of fever patients; (*b*) the natural reluctance of parents and relatives to permit the removal of friends to hospital would be increased owing to the difficult access to the place, as daily inquiries could not be made, and if urgent danger arose the prompt summoning of friends would be more difficult and might entail on the working classes the expense of a vehicle; (*c*) the profession would have greater difficulty in insisting on the removal of infectious cases to a hospital where they would be out of reach of their relatives, and so difficulties might arise in the proper carrying out of the Notification of Infectious Diseases Act; (*d*) owing to its distance the medical service of the proposed hospital would probably be more expensive; and (*e*) a hospital at Purdysburn would be unsuitably placed for the purposes of the training of medical students, and while this deprivation would in the first place fall on the Belfast Medical School, its effects would ultimately re-act upon the entire community. On all these grounds the memorialists pray that the proposal to erect an infectious diseases hospital at Purdysburn should be re-considered, and some other more convenient and accessible site selected.

Proposed Collection for the Cork Hospitals during the Diamond Jubilee Year.

The Earl of Bandon, Lord Lieutenant of the county of Cork, and the Mayor of Cork last week addressed a letter to the newspapers suggesting that as large sums would probably be spent by residents of the city and county in celebration of Her Majesty's Diamond Jubilee year, an effort should be made to pay off the debts due by the various city hospitals. A meeting in furtherance of the project was held last Saturday, and steps were taken to form an influential and representative committee. It is expected that the revenue of the hospitals will be considerably augmented.

Presentation.

Mr. Allsom, L.R.C.P. Edin., &c., who for many years had acted as compounder at the Cork Union Hospital, recently resigned, when certain of his colleagues presented him with a handsome silver tea service.

March 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Buildings of the Faculty of Medicine.

THE new buildings of the Faculty of Medicine will be completed before very long—at least, the demolition of what remained of the old buildings has commenced. It is more than fifteen years since the re-building of the Faculty's premises began, and it has proceeded slowly, the pulling down going on bit by bit simultaneously in accordance with the plan of the architect, M. Ginain. The practical school with its laboratories and dissecting-rooms was built first upon the site of the old Clinical Hospital. With regard to the latter, the first portion built comprised the private rooms of the dean and an enormous building, of which the first floor serves as a library, while the ground floor has for ten years remained unused, its immense rooms being inconvenient for most practical purposes. At present the work of destruction is aimed at the final portions of the old buildings, where M. A. Gautier, the Professor of Chemistry, used to have his laboratories, and where the examination rooms formerly stood. A hundred years ago this building was a church, and one can still see the great lancets for the windows and the remains of the apsidal choir. There also used to be shops on the ground floor, and the names and callings of the shopkeepers can still be read over the façade. The pulling down of the walls exposed to view the examination rooms where so many medical men have undergone the agony of examination, and many students were spectators of the process of demolition.

Death from Hydrophobia.

Two months ago a rich country miller and five other persons who had been bitten by a mad dog came to Paris and underwent the antirabic treatment of the Pasteur Institute. At the end of a month they returned home. A

Hosted by Google

few days ago the miller developed sundry disquieting nervous symptoms and hurried to Paris for treatment, but he died from hydrophobia the same night in the hotel where he had stayed, close to the Institute. The other five who were bitten are doing well.

Deaths of well-known Medical Men.

Dr. de Bossi, the oldest medical man in France, has just died at Havre, aged 104 years, in full possession of his faculties. Dr. Morvan has died at Lannilis, aged 73 years. In 1871 he was a member of the Legislative Assembly, but had for a long time given up politics for the sake of scientific work. He was the first to describe the group of clinical symptoms known as "Morvan's disease," which he considered to be a form of syringomyelia. Since then Dr. Zambaco Pacha of Constantinople, having travelled in Brittany, where Dr. Morvan studied the disease and where it is very common, came to the conclusion that it is an abortive form of leprosy. Dr. Morvan was a corresponding member of the Academy of Medicine.

Oysters and Infection.

The Academy of Medicine has been inquiring into the question of infection by oysters, especially with regard to enteric fever. M. J. Chatin has demonstrated that in natural sea-water the typhoid germ dies rapidly, and that as the oyster picks them up under these conditions they cannot do much harm. Unfortunately, many oyster breeders, with a view to the more rapid fattening of the oysters, lay them down at the mouths of rivers in a mixture of salt and fresh water, and it is this fresh water charged with all manner of germs collected in its course which infects the oyster beds and oysters. M. Chatin recommends that some steps should be taken to guarantee the purity of the fresh water. In the medical world it is suggested that this inquiry has been undertaken with a view to the nomination of an inspector of oyster culture and also to appoint a hygienist who is a *protégé* of the Academy.

The Medical Scandal.

The much-discussed abortion case of last November came on for trial at the assizes on Monday. The defendants are Dr. Boisleux, well known for his gynæcological work and particularly for his paper upon Inter-ligamentous Incision of the Vaginal Wall, and Dr. de la Jarrige, who is accused of having been an accessory. On Nov. 21st last Dr. de la Jarrige was consulted by a young woman named Thomson, an employée of M. Redfern the costumier. She was brought by her lover, M. Mansuy, a friend of Dr. de la Jarrige, and well known in sporting circles under the name of Musany. Miss Thomson complained of abdominal pains, but concealed the fact that she was really pregnant, and Dr. de la Jarrige thereupon sent her to Dr. Boisleux. She next went to a midwife to whom she made overtures to procure abortion, but the midwife refused. Then she returned to Dr. Boisleux, who proposed curetting the uterus, which operation was done at Dr. Boisleux's private house in the presence of Dr. de la Jarrige and M. Mansuy. The curette brought away some placental fragments, and in endeavouring to get these all away Dr. Boisleux perforated the uterus, pulled a knuckle of intestine into the perforation, and the head of the fœtus escaped into the peritoneal cavity. Dr. Boisleux then proposed a laparotomy, but M. Mansuy refused permission for this. During the night symptoms of peritonitis set in, and at 5 o'clock in the morning Dr. Boisleux performed laparotomy, and removed the uterus, but the patient died soon afterwards. The Medical Inspector of Deaths refused the order for burial and regarded the death as a non-natural one. Dr. Boisleux, Dr. de la Jarrige, and M. Mansuy were then all summoned to appear before the Commissioner of Police, and on learning this M. Mansuy blew out his brains. The two medical men attributed the death after operation the one to embolism and the other to peritonitis. A post-mortem examination was ordered, and made by Professor Brouardel, who sent in a report, upon which both medical men were arrested. Investigations were made at the "clinic" of Dr. Boisleux, which was found to be very badly arranged and dirty, and from the books which were seized it appeared that in six years he had had twenty-six deaths from operations. The two medical men declare that they are the victims of a mistake, and were deceived by the patient as to her state of pregnancy. Public opinion and the press are most hostile to both medical men and their "clinics." The accused have been four months in prison awaiting trial, as Professor Brouardel's time has been taken up with the Conference at Venice. The medical world is painfully impressed by this matter, and it is generally regretted that Professor Brouardel was so hasty in demanding the arrest. As a matter of fact, there are no direct proofs of guilt against the accused, and the post-mortem examination showed nothing contrary to their declaration that they had made a wrong diagnosis, as many other gynæcologists have done, especially when their patients were anxious to deceive them. Proof of guilt can only exist in the shape of letters or depositions, and it is uncertain whether any such exist. The case will probably last until Saturday, March 27th, as there are no less than 150 witnesses to be heard.

March 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Balneological Association.

THE meetings of the Balneological Association were held in the Pharmacological Institution from March 12th to March 14th. The President, Professor Liebreich, being ill, the chair was taken by Professor Winternitz of Vienna, who delivered an inaugural address in which he made special reference to the late Dr. Brand of Stettin, the advocate of hydrotherapeutics in enteric fever, and then read a paper on the Treatment of Graves's Disease. He first dealt with the etiology of this condition, mentioning cases in which the symptoms had developed after a severe nervous shock, and gave an account of the results obtained by the administration of the extract of the thyroid and the thymus glands. These results, he said, were far from being satisfactory. There was, moreover, no symptom in Graves's disease which could not be successfully treated by hydropathy or by dietetic and mechanical methods. The increase of the cardiac action and the characteristic tremor require the application of cold bandages on the neck and the back and massage. The diarrhœa is to be treated symptomatically. Milk and vegetable food are beneficial, but butcher's meat is injurious. Professor Winternitz then gave a detailed account of the daily life of the patients under treatment for Graves's disease in his asylum. Although he was, of course, not able to cure every patient, he had always succeeded in relieving the pains. In the discussion Professor Schott of Nauheim said that he was less confident than Professor Winternitz as to the curability of the disease, for patients who had apparently been curred often relapsed. He had never seen any good results from the administration of glandular preparations. He recommended the use of iodide of sodium. Dr. Lindemann of Heligoland then spoke on the action of sea bathing in diseases of the stomach. The majority of practitioners, he said, held it to be an established fact that sea bathing was not useful in such complaints, but this opinion was only correct to a certain extent. Many patients suffering from digestive troubles who had derived no benefit from the mineral springs recommended in these cases were finally cured in Heligoland. The bracing air of the sea acts as a powerful tonic, and the good appetite of patients at the seaside proved its salutary influence on the digestive organs. Irritable patients as a rule do not benefit from the sea air, but other neurasthenics feel very well. Gastric ulcers and carcinoma, of course, became worse, and these diseases are, indeed, rather frequent among the natives. In the discussion some members stated that the recommendations of medical men in matters of diet could not be carried out so satisfactorily in seaside hotels as in inland health resorts. The establishment of homes or special institutions for invalids at the seaside would be necessary if good results were to be generally obtained.—Dr. Lahnsen of Brunnthal read a paper on Agrypnia. After some general remarks on the physiology of sleep and dreams, he said that agrypnia was one of the first symptoms of neurasthenia. More than one-half of a given number of neurasthenic patients complain of sleeplessness. Three forms of agrypnia must be distinguished. The first is very often present in exceptionally active persons, who are able to work from morning till night and to get up very early after only a few hours of sleep; they do not require much sleep, and as a rule do not feel ill although they sleep less than they ought to do. The second form is met with in persons who, although they may be very tired, nevertheless

Hosted by Google

do not fall asleep until several hours after they have gone to bed. This is the genuine form of neurasthenic agrypnia. In the third form the patients fall asleep at once, but awake again very soon. With respect to treatment, Dr. Lahnsen was of opinion that hypnotics should not be used, except in acute agrypnia. Chronic forms must be treated by dietetic and hygienic methods. A stay in a small, quiet country place is to be specially recommended to neurasthenic patients. In the discussion it was pointed out that nervous people are apt to exaggerate their sleeplessness, and that it is doubtful whether agrypnia is to be regarded as a symptom or as a cause of neurasthenia.—Professor Baginsky read a very interesting paper on the Bacteriological Examination of the Water in the "basin baths" of Berlin. He mentioned that he had met with several cases in which children were attacked with enteric fever after having made use of public baths. The chemical analysis of water from the baths did not show any remarkable alteration. He then made microscopical examinations of water taken from several well-known public baths both before and after use. In one of these establishments where the water-supply is derived from wells, and the bath is cleaned every day, the recently admitted water contained many bacteria. After twelve hours, when 200 persons had used the bath 90,000 germs were found per cubic centimetre of water; and after twenty-four hours, when 549 people had been in the bath, 270,000 germs per cubic centimetre were found. The bacteria observed in the water were the following: Bacterium coli commune, proteus vulgaris, bacillus subtilis, bacillus aquatilis fluorescens, staphylococci, and sarcina. In animals the first mentioned bacillus proved to be virulent. Professor Baginsky was of opinion that bathing establishments should be under a stricter control, that there should be a constant inflow of fresh water during the time of bathing, and that bathers ought to rub their skin with a brush both before and after being in the water. Dr. Kisch of Marienbad said that in watering-places the conditions were rendered worse by the fact that the bathers were sick people. The use of large baths ought to be restricted and single bathing ought to be the general rule. Some members doubted whether the germs present in ordinary water would also be found in mineral springs.—Dr. Mendelsohn of Berlin read a paper on the Treatment of Renal and Vesical Calculi by the Water of Mineral Springs. The chemical agents which dissolve calculi in test tubes are useless in the living organism. The good results obtained in lithiasis by the use of mineral waters do not depend on their solvent power, but on their diuretic action. To induce free diuresis must be the principal object of treatment. Calculi probably commence from crystals deposited from very concentrated urine; it is an error to suppose that they originate in uric acid crystals adhering to coagulated albumin. In the discussion Professor Winternitz remarked that alkalinity of the urine must be combated by vegetable food; according to him an infusion of birch-leaves is very efficient in the removal of calculi.—Dr. Ziegelroth then read a paper on the Relation between Scientific Hydrotherapy and the Antitoxin Treatment. His opinion that the antitoxins would soon be things of the past was strongly opposed, even the most fervent balneologists acknowledging that although the exact value of Behring's method may be a matter of controversy, yet they were not entitled to reject it.—The other papers were read by Dr. Hansemann, on Cures and Curability; by Professor Eulenburg, on the Mechanical Treatment of Cerebral and Spinal Diseases; by Dr. Wegele, on the Chemical Examination of the Gastric Juice; by Dr. Schubert, on the Influence of Venesection on Diseases of the Skin; and by Dr. Siebelt, on the Winter Climate of the Silesian Mountains.

March 23rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Parliament and the Profession.

IN his delightful "Memoirs of an ex-Minister" the late Lord Malmesbury goes out of his way to compliment practitioners of medicine on their sagacity in politics, and cites an instance where he distinctly benefited by taking the opinion of a well-known metropolitan consultant on a question before Parliament. Continental experience goes far to confirm his lordship's judgment, and in no nationality more than the Italian. "Legion" is, in truth, the appropriate name for the far-seeing and patriotic publicists and statesmen who have contributed to the unity and independence of Italy. It was Giovanni Lanza, a general practitioner in Piedmont, who was Victor Emmanuel's trusted political adviser during a very critical time, and who, as Premier of the Right, conducted Italy to Rome in 1870. It was Agostino Bertani, the Genoese surgeon, who headed the medical department in Garibaldi's various expeditions and who, before he died, gave his country the "Codice Sanitario" which revolutionised and made uniform her whole system of State medicine. In a more recent decade it was Guido Baccelli who held the portfolio of Public Instruction with such advantage to the higher or professional education; and in the elections now going on throughout the kingdom the medical candidates (of whom there are forty) are conspicuous, so far as their printed addresses enable one to judge, for the enlightenment and public spirit which inspire their appeal to the constituencies. Some of their names are well known to readers of THE LANCET as contributors to its pages—for instance, Count Guido Tizzoni, Professor of Pathology in the University of Bologna and Director of the Pathological Institute attached to the same seat of learning, whose monograph on the Bacillus of Tetanus in your columns is still authoritative, and whose antitoxin (in the discovery and preparation of which he had for coadjutor Eugenio Centanni of Florence) is now well known to the profession. Count Tizzoni is contesting the Vico Pisano division of Pisa in the Liberal interest. Then there is Dr. Giovanni Battista Queirolo, who holds the chair of General Clinical Medicine in the Pisan University, whose intervention at the yearly professional congresses has often given THE LANCET occasion to notice his originality of view in *quæstiones vexatæ* of diagnosis and treatment and his power of criticising adverse positions or of vindicating his own. He, too, comes forward in the promotion of Liberal principles and for the constituency of Rapallo on the Riviera Ponente. Again, there is Dr. Antonio Celli, Professor of State Medicine in our University and Director of the Hygienic Institute, whom many of your readers must remember as one of Italy's ablest representatives at the International Congress of Hygiene and Demography held in London six years ago, and whose subsequent professional visits to our provincial schools have fructified in many practical reforms in his country's sanitation. He is the unopposed candidate, once more in the Liberal interest, for the electoral division of Cagli in the Marches. Milan, moreover, will in every probability return two medical candidates—Dr. Gnocchi-Viani and (all but certainly) Dr. Malachi De Cristoforis, whose efforts to rehabilitate the hygienic conditions of the Lombard capital have been so far successful as, for one thing, to have almost stamped out small-pox by rigorous vaccination and re-vaccination, and who, if adequately supported, would long ago have endowed it with the blessing it sorely needs—a pure and abundant water-supply. The former seeks election as a Socialist and the latter as an advanced Liberal. The University of Modena sends as Liberal candidate for the first electoral division of Pistoia its Professor of Balneology and Hydrology, Dr. Paolo Casciani, whose connexion with the thermal establishment of Monte Catini is widely known through treatises reviewed in THE LANCET, and whose efforts in Parliament to develop Italy's resources in such health resorts are among the grounds on which he appeals for the suffrages of the Pistoiesi. Medico-psychology contributes an able publicist in Professor Silvio Venturi; and criminal anthropology a redoubted advocate of root-and-branch educational reform in Professor Napoleone Colajanni, the former contesting Cologna Veneta, in the province of Verona, the latter Castrogiovanni in Sicily. Both these candidates, if returned, will have the coöperation in Parliament of Professor Enrico Ferri of the Roman school, who, by profession a jurist, is so far medically equipped as to make him Professor Lombroso's henchman at anthropological congresses and also at criminal trials, civil and military. He stands for several constituencies and is more than likely to be returned as many times over. Naples has at least one of its professional staff in the field—Dr. Francesco Fede, who holds the chair of Pathology and Clinical Medicine in the University, and who seeks re-election for Riccia (Campobasso). Rome, as might be expected, sends forth many candidates from its school—the Commendatore Gaetano Semeraro, its Rector Magnificus, who contests Castellaneta (province of Lecce);

Hosted by Google

Dr. Felice Santini, of the Navy Medical Staff, and Dr. Guido Baccelli, Professor of Clinical Medicine in the University Institute and perpetual President of the Accademia di Medicina. He has a Socialist barrister as an opponent for the third electoral division; but all the omens point to his success. He was entertained at a banquet the other day by his committee, and as his speech on the occasion was one of the most memorable evoked by the electoral struggle now in progress I may refer to some of its more interesting passages. Dwelling on the *Esercito e Scuole* (army and schools) he showed how, under the Continental system, the army is efficient in proportion to the intelligence or education of its constituents, and echoed the saying of Mommsen that Germany won her triumphs in 1870–71 by her universities. "The army is the reflection of the people, and the people must be educated in a military sense from the schools upwards." For this end he always when in office worked hand-in-hand with the War Minister, while as to education itself, whether elementary or academic, his watchword was ever "Thorough." The attainment of this ideal he showed to be Italy's surest means of economy—of lightening those outlays which are her chief source of weakness. As to the universities, again, he has always striven for their absolute autonomy. *L'autonomia universitaria*, he repeated, is the one safeguard against the troubles so recently to be deplored. "Liberty of teaching, liberty of study and research, leading up to examinations conducted stringently and impartially by the State—by this means alone will the public be guaranteed a duly qualified medical man, lawyer, or engineer." Some of his professional illustrations were happy, as when he described the European Governments as agitated by "insomnia due to political hyperæsthesia," while that of Italy under the present control was "anæsthetised." His arguments in favour of decentralisation were felicitously drawn from the inter-dependence of stomach, liver, heart, and brain, and at one episode of his review of society he hit the blot and its sequelæ by a reference to "sloughing phagedæna." His audience, largely medical out of a total of 375, enjoyed the apt similitudes, as also the frequent citations, none of them hackneyed but all the more effective, from the Latin poets. The whole speech, from its intellectual breadth, its impartiality, its admirable good temper, and its literary polish, has been widely commented on by political organs of every shade and certainly bears out the remark I began by quoting from Lord Malmesbury that the medical contrasts not unfavourably with any sister profession for the sagacity and even-mindedness it brings to bear on the politics of the day.

March 21st.

Obituary.

WILLIAM BOYD, J.P., M.R.C.S. ENG., L.S.A.

MR WILLIAM BOYD, whose death at Durham on March 9th we have already recorded, was one of the best known and most highly respected inhabitants of the city. He was a native of Durham, having been born in the parish of St. Nicholas in 1817, a few years after his father had come from Merrington to fill an important position in a woollen factory. Mr. Boyd received a good education at two of the local schools, and having resolved to enter the medical profession he was taken as an apprentice by two surgeons practising in the city, Mr. William Clifton and Mr. George Shaw. Under these gentlemen he was well grounded in the details of a practitioner's daily routine, and he eventually proceeded to London, where he attended University College Hospital for a time, and took the qualifications of a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries in 1842. He then returned to Durham, occupying a house in Leazes-place, and soon acquired a large practice, to which he devoted his best energies for more than fifty years. Mr. Boyd also held numerous public appointments, the duties of which he discharged with exemplary assiduity. He was for a long time medical officer to the workhouse. He was, moreover, the public vaccinator; and on the death of Mr. Shaw in 1871 he was elected surgeon to Durham County Prison, a post which he retained until the management of all the prisons in the country was taken over by the Government. He was also medical officer of health for the parishes of St. Nicholas and St. Oswald. Mr. Boyd possessed considerable business capacity, extensive general information, and much intellectual power. He was a man of few words, and took little account of class distinctions in his demeanour towards his patients, displaying similar courtesy to rich and poor alike. In the municipal life of Durham Mr. Boyd played a large part, his connexion with it being of such duration that of late years he was the "father of the corporation," having outlived all those with whom he was associated on his first entering into public life. He was councillor for the North Ward from 1849 to 1859, when he retired on being elected alderman, to which more important office he was always re-elected without opposition until his resignation a few years ago on account of failing health. Mr. Boyd's high place in the estimation of his fellow townsmen is sufficiently shown by the fact that he was elected to the mayoralty on four occasions—namely, in the years 1857, 1860, 1865, and 1888. During his first term of office he had the duty of presenting an address to the Queen on the occasion of the marriage of the Princess Royal. In 1890 the corporation conferred on him the honorary freedom of the city, and requested his acceptance of the oil painting of himself which now hangs in the Town Hall. Mr. Boyd has left a widow and a son. The funeral took place on March 13th at St. Nicholas' Cemetery in presence of a large company of mourners.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in March in the under-mentioned subjects:—

Surgery—E. C. Bailey, King's College; G. E. Brooke, Cambridge and London; R. Holt, Royal College of Surgeons in Ireland; G. F. May, McGill University; J. Ponsonby, Guy's Hospital; L. W. Seymour, St. George's Hospital; and A. Stein, Middlesex Hospital.
Medicine. Forensic Medicine, and Midwifery.—H. M. Church, McGill University; J. F. Fox, Cork and Westminster Hospital; F. T. Knott, London Hospital; and W. L. G. Morgan, St. Thomas's Hospital.
Medicine and Forensic Medicine.—C. H. Church, McGill University; H. Lewkowitsch, Breslau; and M. S. Martin, Calcutta.
Medicine and Midwifery.—E. L. C. Muspratt, King's College.
Medicine.—J. Cater, King's College; A. J. Pedley, Birmingham; A. W. Robertson, St. Bartholomew's Hospital; and E. G. Smith, London Hospital.
Forensic Medicine and Midwifery.—W. Mawer, St. Bartholomew's Hospital; and A. R. O'Flahertie, London Hospital.
Forensic Medicine.—E. J. E. Coop, Birmingham and St. Bartholomew's Hospital; and A. M. Weir, Royal Free Hospital.
Midwifery.—C. I. Ellis, Aberdeen and St. Thomas's Hospital; A. Gandier, Toronto; C. G. Schultz, St. Mary's Hospital; and A. Stein, Middlesex Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—Messrs. Brooke, Ellis, Gandier, Morgan, Pedley, Ponsonby, Robertson, Seymour, Smith, and Stein.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. T. Rosenheim, *privat-docent* of Internal Medicine, has been granted the title of Professor.—*Bonn:* Dr. H. Wendelstadt of Cologne has qualified as *privat-docent* of Pharmacology.—*Budapest:* Dr. Imrédy, Dr. Tanszk, and Dr. Fodor have qualified as *privat docenten* of Medicine, and Dr. Riegler as *privat-docent* of Hygiene.—*Freiburg:* Professor von Kries, who had been offered the chair of Physiology in Berlin in succession to Dr. du Bois Reymond, has decided to remain in Freiburg.—Dr. Ernst Gaupp has been appointed Extraordinary Professor of Embryology.—*Halle:* Dr. H. Reineboth has qualified as *privat-docent* of Internal Medicine.—*Heidelberg:* Dr. Kaiser has been appointed Extraordinary Professor of Physiology.—*Lemberg:* Dr. Ladislaus Szymonowicz of Cracow has been appointed Extraordinary Professor of Histology and Embryology.—*Marburg:* Dr. von Heusinger has been appointed Extraordinary Professor of Forensic Medicine and Dr. Wernicke has been appointed Extraordinary Professor of Hygiene.—*Moscow:* Dr. de Strauch has qualified as *privat-docent* of Gynæcology.—*Munich:* Dr. H. Gudden has qualified as *privat-docent* of Pharmacology.—*Turieff (Dorpat):* Dr. Chirvinski of Moscow has been appointed Professor of Pharmacology and Dietetics, in place of Professor Kobert, who has gone to Görbersdorf.—*Warsaw:* Dr. A. Shcherbak has been appointed Professor of Mental Diseases, and Dr. J. Federoff has been appointed Professor of Gynæcology.

Hosted by Google

THE council of the Midland Branch of the British Dental Association met on March 20th in the Leeds Medical School. The members of the branch resident in that part of the county of Yorkshire also met in the same building, and the company were cordially welcomed by Mr. Scattergood, dean of the medical department of the Yorkshire College.

LINCOLN COUNTY HOSPITAL. — The report presented at the annual meeting of the Lincoln County Hospital showed that the total income during 1896 was £4933 and the expenditure £4814, and the balance due to the treasurer was reduced from £688 to £569. With the view of giving greater security against fire a Merryweather rotary pump was ordered to be provided, and the water service was increased.

BRISTOL EYE HOSPITAL.—The annual meeting of this institution was held, under the presidency of the Mayor, on Feb. 24th. During the past year 4637 new individual out-patients came for treatment, being 300 in excess of 1895, and 379 serious cases were admitted into the wards. The daily attendance of patients at the hospital is about 100. The statement of accounts showed that the income for the year was £1522 and the expenditure £1992, leaving an adverse balance of £470. Dr. Richardson Cross stated that there were 130 towns and villages outside Bristol from which patients had been received, and he hoped the residents of those places would think of the Bristol Eye Hospital when they were considering the claims of medical charities.

THE NEW WORKMEN'S CONVALESCENT HOME IN SUSSEX.—The model convalescent home at Rustington, near Littlehampton, which was fully described in THE LANCET of March 20th, was opened on that date by the Bishop of Chichester. A special train from Victoria brought over 300 guests interested in the scheme, and they were entertained most hospitably by Mr. and Mrs. Henry Harben, the former of whom erected the home and has liberally endowed it. The Bishop laid a memorial-stone and unlocked the door of the home, and after a short service in the hall he declared the institution open. Subsequently at luncheon the toast of Mr. Harben's health was heartily received, and then the company had an opportunity of inspecting the home and its pleasant surroundings. The home is to be conveyed to the Carpenters' Company of London.

BIRKENHEAD MEDICAL SOCIETY.—At a meeting of the above society held on March 19th, Dr. R. Sydney Marsden, President, being in the chair, a discussion on Gastro-enteritis in Children was opened by Mr. G. S. Stansfield, who gave statistics drawn from the experience of Tranmere Workhouse as to the prevalence of this disease and the relative mortality. He also quoted statistics of the comparative mortality in various foundling hospitals with diverse methods of feeding. He pointed out the necessity of correct feeding with regard to material, quantity, and time, and expressed his appreciation of the rules for the feeding of infants drawn up and printed as a leaflet by the Liverpool Children's Infirmary. He entered at some length into the question of the contamination of milk, and concluded by giving an epitome of medicinal treatment. The President, Dr. Pinkerton, Dr. Brien, Mr. Wilkinson, and Dr. Harris took part in the discussion, and Mr. Stansfield replied.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY. — The annual meeting of the Chesterfield and North Derbyshire Hospital and Dispensary was held on March 11th in the Market Hall, Chesterfield, Mr. R. T. Gratton presiding. The report showed that during 1896 there were 312 in-patients admitted, of whom 19 died; there were also 2049 out-patients. The income for the year was £1889 and the expenditure (including £200 transferred to the endowment account) was £1885. None but surgical cases are received in this hospital; space does not permit of medical wards being opened, and it appears that the workhouse hospital is the only institution in the town available for the treatment of medical cases. After various speakers had expressed their views on the subject, it was eventually decided, on the motion of Dr. Rose, that five members of the board of management should meet a like number of representatives appointed by the town for the purpose of discussing the best means of providing for the treatment of medical cases.

NEWTON ABBOT COTTAGE HOSPITAL.—Mrs. Allaline Fisher of Abbotsbury, Newton Abbot, who recently died, has left £2000 for the furnishing of Newton Abbot Cottage Hospital. A little time ago Mrs. Fisher gave £5000 towards the building of this institution in memory of her husband.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—At an examination for the Diploma in State Medicine the following candidates have passed with honours: Fredk Alex. Craig, M.B.R.U.I., and John Edwin Hancock, M.R.C.S.Eng., L.R.C.P.Lond.

A HOME OF COMFORT FOR THE DYING.—A Home of Comfort for the Dying has been opened at "Dowran," Southsea, in charge of the Winchester Diocesan Deaconesses, for the reception of better-class patients, clergy, missionaries, church workers, nurses, governesses, &c., who are suffering from progressive and incurable disease. Patients, when possible, have to pay towards their support, but payment is not a *sine quâ non*. Application should be made to the Mother Superior, St. Andrew's Home, Portsmouth.

CHELTENHAM GENERAL HOSPITAL.—The annual meeting of this hospital was held on March 17th, under the presidency of Colonel Croker-King. The medical report showed that the number of in-patients was 920 and of out-patients 4844, the latter being an increase of 308 on the year. The average cost of each in-patient was £3 15*s.* 4*d.*, and of each out-patient 3*s.* 3*d.* The cases treated at the branch dispensary were 4033, at an average cost of 2*s.* 5½*d.* The private nursing cases were 263, and the amount received £1038. There was no falling off in the amount of the subscriptions to the hospital. The church collections showed a decrease of £44, and the Hospital Saturday Fund an increase of £17.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—A meeting thoroughly representative of town and county was held at Newport on March 17th to consider the best means of commemorating the Queen's Diamond Jubilee. Lord Tredegar presided, and among those present were the Duke of Beaufort, the Mayor of Newport, and Dr. Garrod Thomas. A resolution was adopted in favour of a joint town and county effort to erect a new hospital, to be located at Newport, the site for which has been given by Lord Tredegar, and towards which an offer of £5000 has been made by Dr. Garrod Thomas conditional on the public subscribing £15,000, or, as an alternative, £1000 for every £3000 subscribed by the public. The meeting was of a most unanimous character and promises of £1045 were given for additions to a fund which previously amounted to £4500.

THE DIFFUSION OF SMALL-POX.—There was no death from small-pox registered in the county of London last week, and the cases admitted to the hospital ships at Long Reach were only 2 in number, as against 18, 6, and none in the three preceding weeks. On Saturday last there were 29 patients on the ships, as compared with 43 a fortnight previously. Some concern has lately been felt by the Neath urban district council by reason of the fact that small-pox has appeared in a gipsy camp in the neighbourhood, the members of the camp persisting in roaming about. Small-pox has broken out in a Cardiff hotel, four cases having been removed to the borough sanatorium. Revaccination has been performed at the hotel among the servants and others, and all other precautionary measures have been adopted.

TORBAY HOSPITAL, TORQUAY.—The annual meeting of this hospital was held recently at Torquay under the presidency of Mr. W. Kitson, J.P. The report showed that 330 in-patients had been admitted in 1896, against 342 in 1895. 497 minor accidents and emergencies had been treated, 60 in-patients and 442 out-patients were treated by the honorary ophthalmic surgeon, and 509 dental cases were treated by the honorary dental surgeon. The provident dispensary, which has been placed upon an entirely fresh basis, had 1156 patients on Dec. 31st, 1896. The treasurer's statement showed the institution to be in debt on the revenue account to the extent of £135, although the year commenced with a favourable balance of £3, thus making the excess of expenditure over receipts for the year £138. This unfavourable balance has been fortunately removed by a ball recently given by the Mayor and Mayoress of Torquay.

Hosted by Google

MR. T. W. MORGAN, D.Sc., of Messrs. W. E. Lowe and Co., chemists, 8, Stafford-street, Old Bond-street, W., asks us to intimate to the members of the medical profession that he is not the Dr. Morgan mentioned in the case of Bull v. Morgan.

MEDICAL MAGISTRATES.—The Lord Chancellor, on the recommendation of the Lord-Lieutenant, has placed the name of James Grey Glover, M.D. Edin., of Highbury-place, on the Commission of the Peace for the County of London.—Mr. Thomas Moreton, M.R.C.S. Eng., of Hartford, Northwich, has been placed on the Commission of the Peace for Cheshire.

GENEROSITY.—A letter has been received at the Nottingham General Hospital from Mr. Ernest T. Hooley in which he offers that whatever the Hospital Saturday Committee between now and "Queen's Commemoration Day" (June 22nd next) collect throughout the district participating in the benefits of the hospital, up to 200,000 shillings, he will supplement by an equal amount, the whole to be applied to the fund for the much-needed extension of the hospital, and to be styled "The Hospital Saturday Victoria Fund."

FOOTBALL CASUALTIES.—In a match played at Bedminster, Bristol, between Bedminster and Trowbridge Town, on the 17th inst., a member of the latter team sustained a fracture of his clavicle.—On the same day, during a match at Brighton, a player, the centre half, dislocated his left humerus.—On Saturday last, in a match, Shipley against Luddendenfoot, at Shipley, the Shipley centre three-quarter received a serious injury to one of his eyes, and was at once taken to the Bradford Eye and Ear Hospital, and remained a patient.

DIPHTHERIA IN LONDON.—The fatal cases of diphtheria in London during last week amounted to a total of 37, these deaths being only 1 in advance of the corrected decennial average of deaths from diphtheria in London in the eleventh week of the period 1887–96. This total showed a decided fall from the numbers of the preceding three weeks, which had been 62, 43, and 53 respectively. Only 2 of the deaths were of persons aged upwards of twenty years, whilst 2 were of infants under one year of age. Lambeth and Wandsworth were each credited with 5 of the deaths, and Hackney and Bethnal Green each with 4 deaths; these four sanitary areas therefore accounted for almost one-half of the deaths in the week in the whole county of London. The admissions to hospital during the week numbered 113, as compared with 102. 112, and 97 in the three weeks immediately preceding, 829 patients suffering from the disease remaining under treatment on Saturday last. In the Outer Ring of the metropolis there were as many as 17 deaths registered from diphtheria last week, 3 being in the Edmonton registration district and 5 in the West Ham registration district.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health (Scotland) Bill.

ON Monday, March 22nd, a further attempt was made to get the Public Health (Scotland) Bill through the second reading stage, but, like previous attempts, this one failed. Several Scotch Members made speeches criticising the measure.

General Medical Council Accounts.

The accounts of the General Medical Council and the branch councils for the year ending Dec. 31st last were laid before the two Houses of Parliament this week.

HOUSE OF COMMONS.

THURSDAY, MARCH 18TH.

Beri-Beri in an Irish Asylum.

Mr. Carew asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the present alarming condition of the Richmond Lunatic Asylum in Dublin; whether he was aware that, with accommodation available for only 1000 patients, 1714 were housed there in October last, and that in consequence of this overcrowding beri-beri, a loathsome disease hitherto confined to the densely populated and filthy quarters of Chinese and other Eastern cities, has appeared, and of 113 patients attacked last year seven died up to December last; would he explain why, notwithstanding the repeated protests of two of the members of the Board of Control against overcrowding, no practical steps had been taken by that body to stamp out the disease; and whether, in the circumstances, the Government would see that immediate precautions were taken to prevent its spreading.—Mr. Gerald Balfour replied that the Irish Government had been giving close and constant attention to the accommodation at the Richmond District Asylum and to the outbreak of beri-beri there. The number of patients on the asylum register at the end of 1896 was 1728, of whom 59 were at Portrane. The present accommodation of the Richmond Asylum was for 1393 patients, in addition to which provision had been made for 80 patients at Portrane and for 40 in the residence of the resident medical superintendent (surrendered for that purpose), thus bringing up the present accommodation to 1518. Further temporary accommodation for 220 patients was now being provided at Portrane. The number of deaths from beri-beri at Richmond during 1896 was 8, as against 123 deaths from various other causes. He might observe that the general death-rates in this asylum for 1895 and 1896 were the lowest recorded since the opening of the asylum. In 1895 the percentage of deaths from all causes was only 7·1 and in 1896 7·8, and comparing these rates with the death-rates in the principal English asylums during 1896 he found that, with two exceptions, the rates in the English asylums were much higher than at Richmond. Every effort had been, and was being, made by the Board of Control to stamp out the disease known as beri-beri and to provide adequate accommodation for the patients.

Meat-supply for the Army.

Mr. Powell Williams, answering a question put to him by Mr. Flavin, said that two officers of the War Department, one of them belonging to the Army Service Corps, had visited Ireland in reference to the question of the meat supply to the troops and they were now pursuing their inquiries in other parts of the kingdom.

MONDAY, MARCH 22ND.

Poor-law Officers' Superannuation.

Mr. Ashton asked the President of the Local Government Board whether the information in the possession of the Local Government Board showed that the contributions from salaries of Poor-law officers under the Poor-law Officers' Superannuation Act, 1896, would suffice, or almost suffice, to pay the pensions under the Act; whether his attention had been called to the calculations made by Mr. Thomas Fatkin, an expert, at the request of the Leeds Board of Guardians, and adopted by them on Jan. 13th last, which calculations showed that the contributions of the officers would barely suffice to pay one-third of the cost of the pensions under the Act; and whether, having regard to the fact that a Bill was before the House to extend the provisions of the Act to the officers and servants of other local authorities, he would consider the advisability of having actuarial calculations made out to determine what proportion of the cost of the pensions was likely to fall on the ratepayers in the event of the Bill becoming law.—Mr. T. W. Russell replied to the question, saying that the Local Government Board had no definite information as to how far the contributions from salaries of Poor-law officers under the Poor-law Officers' Superannuation Act would suffice to pay the allowances under the Act; but it had to be borne in mind that in the great majority of cases of officers to which the Act referred the guardians prior to the passing of the Act were empowered to award superannuations without any contributions from the officers. The Act had conferred upon the officers the right to a superannuation—instead of its being optional with the guardians to grant superannuation, as was previously the case—as regards all officers who devoted their whole time to their duties, it being at the same time made obligatory on the officers to whom the Act applied to contribute a percentage of their salaries towards the cost of superannuation. The Local Government Board had seen the communication which Mr. Fatkin had addressed to the Leeds board of guardians, but they could not undertake to have made the actuarial calculations suggested in the last question, and looking to the thousands of authorities to which the Bill referred the Local Government Board did not think there were any data on which any actuarial calculations which could be relied upon could be made.

The London Water Question.

Sir Frederick Dixon-Hartland asked the President of the Local Government Board whether he had seen that since the decision of the House was given against the London County Council acquiring the control of the water supply of London the council had instructed its engineer to proceed with the plans and sections of the Wye portion of the Welsh scheme, at a cost of £1,500; and whether any and what steps could be taken to prevent this expenditure of the ratepayers' money, and if the parties promoting the scheme could be surcharged by the Government or other auditor.—Mr. Chaplin said he had ascertained that the London County Council had, subject to the passing of the annual maintenance vote, assented to the expenditure referred to in the question, and that the expenditure was considered to be authorised by Section 3 of the London Water Act, 1892. The Local Government Board had no authority to intervene to prevent the expenditure; it would, of course, devolve on the district auditor in the case of the payments referred to, as in the case of any other payments by the County Council, to consider whether the expenditure had been legally incurred.

Dangerous Performances.

At this sitting Mr. Jesse Collings introduced a Bill to extend the age under which the employment of young persons in dangerous performances is prohibited. The Bill raises the age of prohibition from fourteen to eighteen years.

TUESDAY, MARCH 23RD.

Experiments on Living Animals.

Mr. MacNeill asked the Secretary of State for the Home Department whether the inspectors appointed for the purpose of securing a compliance with the provisions of 39 and 40 Vict., c. 97, to visit places licensed for the practice of vivisection, had hitherto been persons who either had practised vivisection in the past, or shown the strongest sympathy with the practice of vivisection; were there any of those inspectors who were opposed to the practice of vivisection; and whether he would consider the advisability of not confining the inspection of licensed places for vivisection to inspectors who were advocates of the system?—Sir Matthew White Ridley replied that the inspectors had been appointed by his predecessors without regard to their advocacy of or opposition to the

Hosted by Google

system established by statute under which experiments might be performed on living animals. If occasion arose he should pursue the same policy. The scientific knowledge required in an inspector implied a knowledge of experiments on animals, and he was satisfied that the inspection was carried out with the strictest regard to the law and to considerations of humanity.—Mr. MacNeill asked the right hon. gentleman to say whether all these inspectors were advocates of vivisection, because he was told they were.—Sir Matthew White Ridley said he had told the hon. member that they were all acquainted with the most humane method of conducting these experiments. He was not able to say whether they were advocates of the law as it stood or whether they desired any change in it, but he was persuaded that they could not see whether operations were conducted according to law unless they employed professional gentlemen who knew something about the matter.—Mr. MacNeill then asked the right hon. gentleman whether his attention had been directed to the account in the press of a soirée to which 400 guests were invited in honour of the completion of the new laboratories in connexion with St. George's Hospital Medical School, the report stating that in the physiological laboratory were displayed illustrations of new methods employed in the serum diagnosis of cholera and diphtheria; and whether St. George's Hospital had a licensed laboratory for the performance of experiments on the bodies of living animals; and, if so, why had not this hospital been included in the last return of places licensed for vivisection.—Sir Matthew White Ridley replied that he had seen a newspaper account of the reception referred to, but he did not gather from it that anything illegal took place. There was no licensed laboratory at St. George's Hospital.

Metropolitan Poor-law Children.

Mr. Bemrose asked the President of the Local Government Board, with reference to the proposed order for a new sick children's board, how many replies had been received from boards of guardians and managers, and how many of these expressed approval of the order as it stood.—Mr. Chaplin replied that since the date of the Conference he had received communications from seven boards of guardians out of thirty and two school districts out of six. Three out of the seven boards of guardians either approved the draft order or suggested as an alternative that the Metropolitan Asylums Board should take charge of the cases; one board preferred the Metropolitan Asylums Board if there was to be any change at all to which it was opposed; another suggested that the classes referred to should be assigned to some school or group of schools, and the remaining two objected. Of the two school districts, one approved and the other objected.

ROYAL INSTITUTION.—3 P.M. Right Hon. Lord Rayleigh: Electricity and Electrical Vibrations.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

THE YARROW CONVALESCENT HOME FOR CHILDREN.

OUR readers will remember the munificence with which Mr. Yarrow founded and endowed a delightful convalescent home at Broadstairs for children in 1895. The report for seventeen months of work done is before us and is highly satisfactory. The home is founded for the benefit of children of respectable parents with limited means and confronted with exceptional circumstances of sickness, implying the need of change and sea air for convalescence. Such circumstances often greatly embarrass those who under all ordinary circumstances live quite independently. A table is given of the position or occupation of the parents. The predominant numbers are those of clerks in banking, insurance, and commercial houses, but nearly all classes are included in Mr. Yarrow's beneficence. He does the duty of entertaining convalescents in a complete sort of way, heading his report with an unwonted line in such documents, "No subscriptions are required for this institution, which is fully endowed." All he asks from the profession and the public is to send him fit cases of the class whose benefit he contemplates. We congratulate Mr. Yarrow on having relieved in seventeen months 661 children, 114 of whom were children of widows, or orphans. His action, like that of Sir Blundell Maple, shows that when "wealth accumulates" men do not necessarily "decay."

"A SUCCESSFUL SOCIETY!!"

MRS. THEODORE MONRO, the hon. secretary of the London Anti-Vivisection Society, writes to us under date March 18th, and asks us to inform her how her society is to proceed so as to obtain a conviction of "vivisectors" for "cutting up animals alive" without anæsthetics, and maintaining that it is legal to cut up animals alive under these circumstances. She also says that in the return printed on August 6th last some 3000 experiments were down as having been made without anæsthetics. No doubt there were, but the animals were not "cut up alive" any more than babies who are vaccinated are cut up alive. If Mrs. Monro will look at the *Times* of March 14th and study the Home Secretary's reply to Mr. MacNeill on that occasion and on March 23rd also, she will learn the nature of the experiments carried out without anæsthetics. We might further remark that anti-vivisection societies might do some good to themselves and gain some respect if they would only take the trouble to verify their references and not make mis-statements, to call them by no stronger name.

A Locum-tenent puts a hard case to us. We think on the whole that he is entitled to be refunded the money he has spent, but he will remember that it is usually as much annoyance to a principal as to a locum-tenent to be disappointed in such engagements. Therefore, before claiming anything he must make it clear that the conveyance in question was one of which a man of his build, weight, and age ought not to have been asked to make use.

Viator should write to the sanitary authority and complain. By so doing he will be putting the neighbourhood under an obligation.

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—The best antiseptic I know of for vaginal and uterine irrigation is a solution of silico-fluoride of potassium. This can be used in stronger solution than was advised by the introducers of salufer, and I have never seen any bad effects from the use of the saturated solution. But I reserve the strong solution for the treatment of cases already infected, as on a raw surface it causes smarting. I am of opinion that corrosive sublimate often does harm by lowering tissue vitality just when it is most required. I have had better results with salufer in the treatment of bad compound fractures, foul and extensive wounds, and the like, than I have observed under any other treatment. It is the only chance in puerperal fever of a severe type, and should be persevered with, but in such cases the practitioner who is content with one irrigation in the twenty-four hours gives neither the patient nor the drug a chance. In conclusion I can honestly say that I do not remember a case in which I have found reason to question the efficacy of the silico-fluoride. I am, Sirs, yours, &c.,

Coventry, March 14th, 1897. F. FAULDER WHITE, F.R.C.S. Eng.

To the Editors of THE LANCET.

SIRS,—I should like to add a word or two to the interesting discussion which is now taking place in connexion with the above subject. Corrosive sublimate, biniodide of mercury, and carbolic acid, especially for external antiseptis or asepsis—i.e., of the hands, instruments, &c.—are, of course, most excellent, but I think for vaginal and intra-uterine douching permanganate of potash should have the preference. Given a really severe case of puerperal fever or of sapræmia, call it which you will, frequent douching—i.e., every three or four hours—with a hot solution of permanganate of potash is most important. Apart from the danger from absorption of carbolic or mercury in using, say, a 1 in 2000 solution of the biniodide so frequently, I have certainly noticed in two or three cases, notably in one in which the temperature rose to 106° F. during a relapse, that the temperature was more favourably modified by a fairly strong permanganate intra-vaginal douche than by the biniodide. Very generally it is necessary to use an intra-uterine douche twice daily, and a vaginal douche in between times every three or four hours. This douching should be performed by the doctor himself; it should not be left to a nurse, however skilful she may be, until the patient is practically out of danger. As an adjunct to the above quinine should almost always be given—three grains with ten minims of dilute nitric acid in half an ounce of chloroform water every three hours is a good formula. Five to ten grains of quinine in a cachet may be also given if necessary. Too large an exhibition of quinine given early in the case is liable to produce vomiting and diarrhœa—a most serious contingency. By close personal attention early in the case its duration may be very considerably limited. It has been my habit at the conclusion of a specially difficult case to advise a permanganate douche before leaving; many cases, however, never require douching at all. I am, Sirs, yours obediently,

Chester, March 17th, 1897. HENRY W. KING, M.D. Edin.

A Colleague.—We do not know the terms of our correspondent's agreement. If his employer promised to treat him as a partner, waiving the usual introduction of capital in his favour, then we can understand that he ought to have a voice in the conduct of the practice. But if "A Colleague" was engaged to assist in the work under his principal's direction, it seems to us that it is his duty to perform the share allotted to him, whatever that share may be.

A NEW UNIVERSAL PROVIDER.

THE Universal Information Office is a sanguine body. According to its prospectus, "it will be perceived that information on any subject under the sun can be obtained through this office." We fancy that we could, all the same, pose this office, for to say nothing of the stock puzzle, "What was the name of Moses' mother-in-law?" there are many other insoluble problems. We notice that the office undertakes to give medical information, and that inquiries from ladies may be addressed to "Lady Medico, care of Universal Information Office, when they will be attended to by a fully qualified lady doctor." Diagnosis and treatment by correspondence are, to say the least of it, risky when the information is supplied only by the patient.

Steps is strongly advised not to advertise in the local papers. Notice of change of address should for obvious reasons be sent only to a practitioner's own patients.

"AN INSOLENT ADVERTISEMENT."

To the Editors of THE LANCET.

SIRS,—My attention has been called to a paragraph in THE LANCET of March 13th concerning myself and my manner of conducting my business. Your mode of expression would make it patent to any unprejudiced person that the article was actuated by other motives than those which are supposed to influence a responsible paper. I am at liberty, I assume, to pursue my calling in my own manner, provided I use [only legitimate and honourable means; and far from my circular having given offence to the medical profession, allow me to assure you that I have been most agreeably surprised at the results. I presume that you will have the justice to insert this protest against such an abominable misuse of your columns as the article referred to. I am glad to find that instead of adopting the advice tendered to them in the paragraph referred to—i.e., to write me a rude letter telling me to mind my own business—many members of the faculty still continue to send me their patients for me to correct their errors of refraction and accommodation and supply suitable lenses, and some of them even go so far in supporting what you are pleased to refer to as my insolence and impertinence by coming to me for spectacles (made up to my own prescription after examining their eyes) for their own use. The use of the words "*insolent*" and "*impertinence*" *in your paragraph is calculated* to hold me up to contempt and ridicule, and I regard them as distinctly libellous; and as my circular in no way justifies such language being used I must ask you to withdraw that portion of your criticism. I in no way do, nor could, object to a fair comment, but I contend you have far over-stepped the fair line. I await the issue of your next number and the manner in which you deal with this matter. Unless you dispose of it to my satisfaction I reserve to myself every right I may possess. Yours, &c.,

FRANK HOWARD.

83, Great Portland-st., London, W., March 22nd, 1897.

*** We subjoin Mr. Frank Howard's circular.—ED. L.

SIGHT SCIENTIFICALLY TESTED FREE OF CHARGE.

Patronised by the Central London Ophthalmic Hospital; the Miller Hospital, Greenwich; the St. Saviour's Union, Walworth; the Uxbridge Union; the St. Marylebone Infirmary; the Metropolitan Hospital Sunday Fund; and the Leading Members of the Medical Profession.

FRANK HOWARD,
LATE MANAGER TO E. S. PICKARD AND CO.,
Consulting Ophthalmic Optician.

83, Great Portland-street, London, W., Jan. 1st, 1897.

DEAR SIR,—I have much pleasure in informing you that I have recently added very considerably to my plant and staff, and in future shall be able to execute all orders for spectacles, or any optical instruments, with greater promptitude than, and the same accuracy as, heretofore.

I have a consulting room and dark room fitted with electric light and all the latest improvements, together with all necessary lenses, frames, types, and instruments, which I shall be happy to place at your disposal any time you wish to examine a patient here; or if you kindly send to me any patient whose errors of refraction or accommodation require correction I should be glad to diagnose the case, and submit my prescription to you for verification and approval free of charge. Should you entertain my offer I would like to forward you for perusal copies of a few of the many testimonials and recommendations I hold from medical men (mainly in practice in the West-end of London), who are good enough to entrust me with their eye work.

I need hardly say the testimonials, &c., referred to are not for general publication, but were given to me upon the distinct understanding that they were only shown to members of the medical profession.

In all cases of patients introduced to me by the faculty I make the examinations and take all measurements personally.

Hoping to be favoured with a share of your patronage.

I remain,
Faithfully yours,
FRANK HOWARD.

W. H.—The qualifications would come up to the Board's requirements.

Hosted by Google

THE PRUDENTIAL ASSURANCE COMPANY, LIMITED.

THE vast extent of the business transacted by the Prudential Assurance Company proves that the duty of providing for the future is being more and more realised by the public. The report and accounts for 1896 have now been circulated, and show a very considerable increase in the operations of the company over those for 1895. The number of policies issued in the ordinary branch during the year was 64,241, assuring the sum of £6,507,820 and producing a new annual premium income of £354,526; the premiums received during the year were £2,543,262, being an increase of £239,249 over the year 1895; the claims of the year amounted to £588,874; the number of deaths was 4598, and 365 endowment assurances matured; the number of policies in force at the end of the year was 455 795. In the industrial branch the premiums received during the year were £4,578,793, being an increase of £226,168; the claims of the year amounted to £1,706,481; the number of deaths was 183,959, and 1630 endowment assurances matured. The total number of policies in force at the end of the year was 12,130,542; their average duration is almost exactly eight years The assets of the company in both branches are £27,059,111, being an increase of £3,143,221 over those of 1895. Of this sum £5 950,000 are invested in loans on the security of county council, municipal, and other rates. The company's endowment assurances and other forms of making provision for old age are largely taken advantage of by the public, the number of policies securing benefits at the age of sixty years and upwards being over 550,000, and securing capital sums exceeding £23,000,000. The jubilee of the company will be reached in the year 1898, and the directors recommend £50,000 to be set aside out of the surplus shown for 1896 to be applied for the benefit of the in-door and out-door staffs. The affluent circumstances of the company are no doubt in a great measure due to the skill and care of the medical referees, whose services, all things considered, seem to deserve some pecuniary recognition out of the surplus mentioned.

M.B.—It would have been more in accordance with professional etiquette if B. had ascertained A.'s position before accepting the invitation of the club.

THE EXTRACTION OF WANDERING NEEDLES.

To the Editors of THE LANCET.

SIRS,—*A propos* of the extraction of needles from the human body under anæsthesia and with a cutting operation—the terrors of a nervous subject—will you permit me to mention a simpler and more expeditious method, applicable wherever the tissues are lax and yielding, and when the needle is obviously a "traveller," and therefore *must* have a point. Provide two firm corks of moderate size and a pair of small pointed scissors, if forceps are not at hand. Apply the corks to each extremity of the foreign body, make a quick, decided thrust of approximation in the direction of its length, and the needle will be found to have perforated the skin and embedded its point more or less deeply within one of them. The grasp of the scissors upon its shaft will ordinarily suffice for an immediate extraction.

My only apprehension would be that in the present attitude of the public towards the profession the patient might not deem a fee necessary for so apparently trivial a service.

I am, Sirs, yours very truly,

Munich, March 16th, 1897. H. WEBSTER-JONES.

Mr. Stephen Coleridge.—If our correspondent knows that being licensed to do some things certain investigators have done other things, he is clearly remiss in not bringing them to account. We do not believe his statements. His letter practically reasserts what we have already contradicted, and our readers are in a position to judge between our correspondent's accuracy and our own.

Mr. W. A. Moynan.—We have made enquiries.

AN ACCOUCHEMENT SET.

WE have received from Messrs. S. Maw, Son, and Thompson, Aldersgate-street, E.C., a specimen of "Maw's Accouchement Set," which that firm have endeavoured to make as complete as possible from the point of view of utility, while supplying every article of the best quality. The price of the set is 25*s*. The articles include waterproof-sheets, towels, binders, napkins, and other things necessary for accouchement under aseptic conditions, together with tabloids of perchloride of mercury, carbolic soap, and carbolised petroleum jelly, &c. With regard to the latter, we are of opinion that glycerine of perchloride (1 in 1000) is best for the fingers. But why is it necessary to supply such a dangerous poison as perchloride of mercury in such a set? The antiseptics to be used should be matters for the practitioner's consideration.

A. M. B. asks if any of our readers can inform him where he can obtain the smallest and lightest one-horse landau or opening brougham, fitted with break for a hilly district in Wales, to hold three inside. The price must be moderate and, if possible, on hire purchase system.

THE DETERMINATION OF THE SEXES.

WE have received a copy of a circular disseminated by a Mr. John Campbell, of the neighbourhood of Penybont, in which he offers to reveal the secret of procuring male or female offspring at will in return for the fee of a guinea. Mr. Campbell is trying to obtain money under false pretences. Possibly he believes in his method, and possibly some lucky guessing has confirmed him in the belief, but the fact remains that he cannot give any reliable assistance to the persons who pay his fee.

Torquay.—Both methods of treatment have their uses in legitimate therapeutics, and as such belong to the practice of the profession at large. It must be left to our correspondent's medical attendant to decide which method, if either, is required in the case in which he is interested, and also to suggest what special medical advice, if any, should be sought.

"MATERNAL IMPRESSION ON THE FŒTUS."

To the Editors of THE LANCET.

SIRS,—With your permission I also would like to record a curious instance of maternal impression on the fœtus which occurred within my own knowledge. The daughter of a medical practitioner whose "studie was (not) but litel on the Bible," and she herself well posted up in Genesis, chap. xxx., ver. 37 *et seq.*, was alone in her house, sitting in a back room, intently preparing her expected baby's wardrobe (expectation six months hence). Her uncle called with the present of a hare, and, after knocking, ringing, and failing to attract attention, walked in, opened the room door where she was sitting, threw in the hare, but "spake not a word." From that moment of fright she "vowed and declared" her belief that some "untoward event" would happen to her baby; and sure enough the unfortunate baby (a girl) was born with the so-called hare-lip. I am, Sirs, yours faithfully,

March 19th, 1897. M.R.C.S., L.S.A.

Inquirer.—We do not know what proof our correspondent has that the gentleman in question is not sincere in his devotional exercises. But we think it a great pity that handbills should be disseminated announcing the appearance of the medical preacher and singer to the public. This proceeding certainly savours to us of improper advertisement, particularly as the medical man is described as Dr. —— and does not appear to possess the degree of a university.

"THE PANCREAS AS AN ARTICLE OF DIET."

To the Editors of THE LANCET.

SIRS,—In reference to the letter of Dr. T. Wilson Parry on this subject in THE LANCET of Dec. 19th, 1896, I may say his experience coincides with mine. Desiring to give a patient, the subject of exophthalmic goitre, thymus gland, I went to a slaughter-house in order to assure myself that I would get exactly what I ordered. When I mentioned sweetbread the butcher said there were three in the calf—the throat, heart, and stomach sweetbread—being the thyroid, thymus, and pancreas respectively, and that the heart sweetbread was very small in the bullock. I am informed, too, that the testicles make a particularly tasty dish and are served under the fanciful name of "mountain oysters."

I am, Sirs, yours truly,

Philadelphia, Feb. 25th, 1897. W. E. ROBERTSON.

Dr L. Kiad.—A table giving the percentage composition of various beef products appeared in an article in THE LANCET of March 7th, 1896.

R. A.—There is no such place.

The Lumleian Lectures

ON

SOME PROBLEMS IN CONNEXION WITH APHASIA AND OTHER SPEECH DEFECTS.

Delivered before the Royal College of Physicians of London,

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,

CENSOR OF THE COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE I.[1]

Delivered on April 1st, 1897.

MR. PRESIDENT AND GENTLEMEN,—The modern interest in, and development of knowledge concerning, aphasia and other speech defects dates from the publication of certain memoirs by Broca, some six and thirty years since, when he attempted to localise what he termed the "faculty of articulate language" in a limited convolutional region of the left cerebral hemisphere. The publication of his cases and conclusions formed the starting point for a whole new series of investigations, whose result has been a remarkable development in our knowledge of the localisation of functions in the cerebral cortex, while the discussions to which these investigations have given rise have materially helped to lead to a better understanding of the working of the complex cerebral mechanisms needed for the carrying on of speech and thought. We are thus at the present day capable of dealing with the subject of speech defects from a much broader basis of discovered facts, as well as with a greater critical insight than was at all possible at, or even long after, the time when Broca wrote his famous memoir. Very much, however, remains to be discovered before the many differences of opinion that exist concerning obscure and complicated points in connexion with the nature and exact mode of production of speech defects are likely to be set at rest.

The special tendency of aphasia and other forms of speech defect to be associated with disease of the left rather than of the right hemisphere is now a well recognised fact. This holds good for right-handed but not as a rule for left-handed persons. In these latter aphasic defects are produced by disease in similar parts of the right cerebral hemisphere. It is believed, therefore, that motor incitations for acts of speech are accustomed to pass off in the main from one cerebral hemisphere, and that whether this shall be from the left or from the right hemisphere becomes determined principally by the increased dominance, or slightly earlier development, of one of them, brought about more or less remotely in association with right- or with left-handedness.

Although we shall here deal with what are known as "acquired defects of speech"—that is, such defects as may have supervened after the power of speaking has been attained—still, it seems desirable that a very brief reference should be made as a preliminary to defects of speech resulting either from congenital disease or from diseases occurring at some date prior to the manifestation of articulate speech. The most important of these congenital defects is deafness, which of itself entails mutism, the individuals thus afflicted being known as "deaf mutes." It must be borne in mind, however, that this mutism or dumbness may also be brought about by absolute deafness occurring from any cause after birth, but before the child has begun to talk, or even after it has learned to talk, up to the fifth or the seventh year. In cases of the latter type the child soon (when left without the customary guidance in articulatory acts derived through the sense of hearing) forgets how to speak and becomes dumb. In addition to this class of cases there are also those of congenital idiotcy without deafness, in which the child never learns to talk. There are also other cases, allied to the last, in which, owing to some intracranial lesion occurring either before, during, or soon after birth, the brain becomes so damaged as to arrest the development of the child's mental as well as of its motor powers. In some of the less severe examples of this type (now commonly spoken of as "birth palsies") that have come under my observation speech has been merely deferred—perhaps till the fourth, fifth, or even the sixth year—and then after a time has become established in a natural manner. In other cases the occurrence of epileptic fits seems to be the retarding cause.

One of the most remarkable cases known to me of deferred speech in connexion with the occurrence of epileptic attacks happened in one of my own patients. In the year 1877 I was consulted concerning the health of a boy who was then twelve years old, and had been subject to epileptic fits at intervals. The first of these fits occurred in infancy, when the patient was about nine months old. Towards the end of the second year the fits seemed to have ceased, the hearing was (as it had been) good, and the child appeared to be of average intelligence—to be well, in fact, in all respects except that he did not talk. When nearly five years old the little fellow still had not spoken a single word, and about this time two eminent physicians were consulted in regard to his "dumbness." But before the expiration of another twelve months, as both his mother and father assured me, on the occasion of an accident happening to one of his favourite toys, he suddenly exclaimed, "What a pity!" though he had never previously spoken a single word. The same words could not be repeated, nor were others spoken, notwithstanding all entreaties, for a period of two weeks. Thereafter the boy progressed rapidly, and speedily became most talkative. When seen by me he spoke in an ordinary manner without the least sign of impediment or defect.

Such a sudden beginning to speak for the first time without previous prolonged trials and failures is a matter vastly transcending in importance the sudden resumption of speech when it has been for a time suspended in consequence of brain disease. No explanation of such a fact seems possible except on the supposition that speech has now become a truly automatic act for human beings, and that if children do not speak at birth this is in the main due to the circumstance that their nervous systems are still too immature. No such untaught acts of speech would, however, be possible unless development had been taking place in a normal manner and unless the auditory sense and intelligence had been unaffected. The occurrence of some emotion may in such a case afford a stronger stimulus, under the influence of which the duly organised speech mechanisms become called into action.

Some curious cases of congenital speech defect were described by Hadden to which the term "idioglossia" has been applied. These children have to a certain extent a language of their own, so that when asked to repeat phrases they make use of definite sounds of their own instead of those proper to the words that should be employed. The sounds which they substitute are said to be always the same for the same words. Some of these patients seem to have been capable of writing correctly from dictation, and they have also shown a fair amount of general intelligence.

THE VARIOUS KINDS OF WORD MEMORY.

According to Sir William Hamilton, "Memory strictly so denominated is the power of retaining knowledge in the mind, but out of consciousness. I say, retaining knowledge in the mind but out of consciousness, for to bring the *retentum* out of memory into consciousness is the function of a totally different faculty (recollection). . . . It is not enough that we possess the faculty of acquiring knowledge and of retaining it in the mind but out of consciousness; we must further be endowed with a power of recalling it out of consciousness into consciousness—in short, a reproductive power (recollection). This reproductive power is governed by the laws which govern the succession of our thoughts—the laws, as they are called, of mental association." This definition of memory implies the notion of an organic change taking place in definite nerve elements on the occurrence of each sensory or intellectual process—that is, the notion of a permanent nervous modification of some kind, plus the possibility of its renewal in more complete form from time to time. We may therefore suppose that on fitting occasions, by the intervention of associational activity, there will be revival in more complete form of something like the original molecular

[1] Lectures II. and III. will be delivered on April 6th and 8th respectively.

Hosted by Google

activity in the nervous elements concerned with the primary perceptional or intellectual process of this or that kind. It is not essential that the memorial revival of the sensory impression or of the intellectual process should after multitudinous repetitions be associated with any distinct conscious phasis. What Sir William Hamilton termed the *retentum* may, indeed, be revived as a mere unconscious nerve action—a link in a perceptive process or in a chain of thought represented merely (as John Stuart Mill put it) by "certain organic states of the nerves." This latter consideration is especially worthy of note from the point of view of the importance of revived kinæsthetic impressions for the guidance of movements, seeing that their revival may be unattended by any distinct conscious phasis; and much the same thing may often be said concerning that memorial recall of words in the auditory centre which immediately precedes speech.

From what has already been said it is evident that "loss of recollection" by no means implies nor is it to be taken as synonymous with "loss of memory." For instance, a patient may be unable to recollect words—that is, spontaneously revive them—for ordinary speech when his memory for such words, nevertheless, exists unimpaired, as may be shown by the fact that the patient is able at once to repeat the words in question when he hears them pronounced or sees them written. His defect, therefore, may consist in a mere lowered activity of the auditory word-centre, in which words are primarily revived during thought. "Loss of recollection" may, in fact, depend upon one or other of two causes: either (*a*) upon some diminished functional activity—that is, diminished readiness to be roused—in the central nerve mechanisms in which the *retentum* is, so to speak, stored or rendered possible of revival; or else (*b*) upon some defect in this or that set of commissural fibres (associational channels). "Loss of memory," however, in the strict sense of the term implies disease of, or serious damage to, the central nerve units in which the particular *retentum* is stored up or registered.

Although it is important from a scientific point of view to make such a distinction as has been above pointed out, it will be found both convenient and practical to let the term "amnesia" stand for loss of recollection as well as loss of memory of this or that kind.

From what has been said it follows, that all cases of amnesia (in the broad sense of the term) ought, from an anatomical or localising point of view, to be divided into two generic groups: (*a*) cases in which there is centric defect (either structural or of marked functional type), with which there will often be loss of memory of words as well as loss of recollection; and (*b*) cases in which there is merely commissural defect (mostly structural), with which there may be loss of recollection of words, but no necessary loss of word-memory. It will be one of my objects in the present lectures to dwell upon the fact (which I pointed out some ten years ago) that it is often in the case of speech defects extremely difficult, if not impossible, from clinical evidence alone to decide whether the underlying lesion or default leading to a particular kind of amnesia be centric or commissural in seat. And yet from the point of view of the localisation of the lesion such a decision may be a matter of much importance, seeing that if the lesion were centric we should look for it in one part of the brain, while if it were commissural it might be found in a region comparatively remote therefrom.

In the case of words there are three distinct kinds or physiological types of memory to be considered—one of them existing in two forms, so as to make four varieties in all. These varieties of verbal memory are as follows:—1. Auditory memory: the memory of the sounds of words—that is, of the auditory impressions representative of different words. 2. Visual memory: the memory of the visual appearances (printed or written) of words—that is, of the visual impressions corresponding with different words. 3. Kinæsthetic memory.[2]—(*a*) the memory of the different groups of sensory impressions resulting from the mere movements of the vocal organs during the utterance of words (impressions from muscles, mucous membranes, and skin)—that is, of the kinæsthetic impressions corresponding with the articulation of different words, which for the sake of brevity I have proposed to speak of as "glosso-kinæsthetic" impressions; and (*b*) the memory of the different groups of sensory impressions emanating from muscles, joints, and skin, during the act of writing individual letters and words—that is of the kinæsthetic impressions corresponding with the writing of different letters and words, which I have for similar reasons proposed to speak of as "cheiro-kinæsthetic" impressions.[3]

The organic seat of each of these four different kinds of word-memory is in relation with its own set of afferent fibres; and the several centres must also be closely connected with one another by commissural or associational fibres, so that the memory of a word or the recollection of a word in one or other of these modes doubtless involves some amount of simultaneously revived activity in one or two of the other word-centres.

The relative intensity or importance (in the process of recollection of words for ordinary speech) of the memorial revival in each of these centres is probably subject to more or less marked variations in different individuals. In the majority of persons, as I pointed out in 1869, the revival of words in the auditory centre is the most potential process, and that which occurs first in order of time. This seems to be now very generally admitted.

THE LOCALISATION OF THE DIFFERENT WORD-CENTRES.

Although I am not a believer in the complete topographical distinctness of the several sensory centres in the cerebral hemisphere, I consider it clear that there must be certain sets of structurally related cell and fibre mechanisms in the cortex, whose activity is associated with one or with another of the several kinds of sensory endowment. Such diffuse but functionally unified nervous networks may differ altogether from the common conception of a neatly defined "centre," and yet for the sake of brevity it is convenient to retain this word and refer to such networks as so many "centres."

Looking to the extremely important part that words, either spoken or written, play in our intellectual life and to the manner in which they are interwoven with all our thought-processes, it becomes highly probable that most important sections of the auditory and the visual sensory centres are devoted to the reception, and consequently to the revival in thought, of impressions of words: and for convenience of reference it is permissible to speak of these portions as auditory and visual "word-centres" respectively. Similarly, there must be what I have termed kinæsthetic word-centres of two kinds (the one in relation with speech-movements, and the other with writing movements) holding a like all-important relation to the expression of our thought by speech and writing. It is possible that the particular parts of the general auditory and visual centres which are in relation with word-impressions may be more or less distinctly defined, like the analogous parts of the general kinæsthetic centre that are in relation with speech or with writing movements. Certain it is that there are some varieties of amnesia in which the part of the visual centre in relation with words seems to be specially at fault (as in "word-blindness"), just as there are other cases in which the part of the auditory centre in relation with words is either wholly or partially inactive (as where we have to do with different degrees of "word-deafness")—in each case without defect in other parts of the general visual or auditory centres, as evidenced by the fact that the persons so affected can still quite well see and recognise ordinary objects, or hear and recognise the nature of ordinary sounds.

In regard to the visual centre as a whole, it seems now to be established that it is more or less diffused through the convolutions on the inner aspect of the occipital lobe and probably even more widely throughout this lobe. The particular part of the visual centre that is most concerned with the appreciation and memorial recall of words—or, in other words, the destruction of which most certainly gives rise to word-blindness—is now fairly well settled. There is much evidence to show that this region corresponds with the

[2] These forms of word-memory were first definitely stated by me to be purely sensory in papers on the Physiology of Thinking (Fortnightly Review, 1869) and on the Muscular Sense (Brit. Med. Jour., April, 1869); and the name "kinæsthetic" was subsequently (The Brain as an Organ of Mind, 1880, p. 543) applied to the complex groups of impressions resulting from movements of this or that part of the body.

[3] Other French writers, as well as Ballet, attribute to Charcot the doctrine that "le mot n'est pas une unité, mais un complexus" (Le Langage Intérieur, 1886, p. 13) because he also dwelt upon these four different kinds of word-memory. Charcot's lectures on Aphasia were delivered in 1883, but M. Ballet will find a full description of these four different kinds of word-memory in my book The Brain as an Organ of Mind, 1880, p. 696, or in the French translation (Le Cerveau et la Pensée, tome ii., p. 222), published in 1882.

angular gyrus either alone or in association with part of the supra-marginal lobule—and therefore that it is situated just beyond the confines of the occipital lobe, and in the region originally assigned by Ferrier, upon the basis of his experiments with monkeys, as the centre for vision as a whole.

In regard to the localisation of the general auditory centre considerable doubt now exists, since the researches of Schäfer and Sanger-Brown do not support Ferrier's allotment of this endowment to the upper temporal convolution. Curiously enough, however, it again happens that the localisation of the part of the general auditory centre most concerned with the appreciation of words (as based upon clinico-pathological evidence in man) must be regarded as being in the posterior half or two-thirds of the upper temporal convolution. The above-mentioned results of Schäfer and Sanger-Brown as to the localisation in monkeys of the general sense of hearing were of a negative character, and cannot be said to afford any definite evidence against this presumption as to the site of the auditory word-centre in man.

The situation of one of the two kinæsthetic word-centres can be rather more certainly localised. Having elsewhere stated very fully my reasons for believing that the so-called "motor centres" of Ferrier and others are really sensory centres of kinæsthetic type by means of which movements are guided,[4] I shall not now attempt to set forth the evidence in favour of this opinion, but shall merely state my belief that Broca's region—namely, the posterior part or foot of the third frontal and the inferior part of the ascending frontal convolutions—is in reality the part of the brain to which I have been alluding as the "glosso-kinæsthetic" centre. The situation of the "cheiro-kinæsthetic" centre cannot be localised with nearly as much confidence. The tendency for some years has been to follow Exner, who believes it to be situated in the posterior part of the second frontal gyrus, though, as we shall see later, the evidence in favour of this localisation is at present extremely scanty. All that can be said on this point, therefore, is that we know approximately where to look for the cheiro-kinæsthetic centre.

For the purpose of our discussion, then, it may for the present be assumed that the two kinæsthetic word-centres are situated as above stated: that the auditory word-centre is situated in the posterior half or two-thirds of the upper temporal convolution; and the visual word-centre in the angular and part of the supra-marginal convolutions. It must also be assumed, upon grounds subsequently to be set forth, that these last-named word-centres are connected together by a double set of commissural fibres. We must likewise suppose that two other important sets of commissural fibres exist between the different word-centres—namely, one set through which the auditory word-centre acts upon the glosso-kinæsthetic centre for the production of speech movements, and another by means of which the visual word-centre acts upon

FIG. 1.

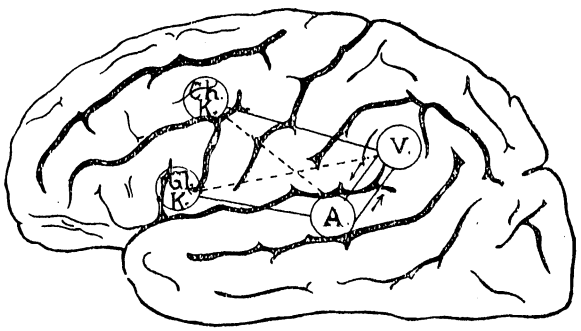

Diagram showing the approximate sites of the four word-centres and their commissures.

the cheiro-kinæsthetic centre for the production of writing movements.

In the study of speech defects it is therefore necessary to consider the effects of lesions in the following situations; (*a*) in the different kinds of word-centres; (*b*) in the different commissures by means of which these centres are connected with one another; (*c*) in the internuncial fibres connecting the two kinæsthetic word-centres with their related motor-centres, in the bulb and in the cervical region of the spinal cord; and (*d*) in these motor-centres themselves which are concerned with the actual production of speech and writing. But before dealing with any of these problems in detail a few other aspects of the questions relating to word-memory, as well as the modes of activity of the brain in perceptive and speech processes require to be considered.

THE PRIMARY SITE OF REVIVAL OF WORDS IN SILENT THOUGHT.

It seems clear that words are the symbols with which our thoughts are inextricably interwoven, and that the revived feelings, ideas, or "images" of words may enter into thought processes by a more or less simultaneous renewal of activity in different regions of the cerebral cortex. There may be a revival of sounds of words as we hear them in ordinary speech; there may be a revival of visual impressions of words as we have seen them in written or printed characters; and, lastly, there may be a revival of the feelings of muscular contractions concerned in the pronunciation of words. Of these modes of "ideal" recall of words the two former are distinct and easily recoverable, while the latter is vague and difficult of conscious realisation. Let anyone contrast his idea of the sound of the word "London," or his idea of the appearance of the word when printed or written, with his idea of the muscular and other feelings associated with the articulation of the same word, and the inferiority in definiteness and recoverability of the latter will at once become obvious.

It is, however, a matter of extreme importance for the due understanding of the different kinds of speech defect and for the success of our endeavours to refer them to defective activity in this or that physiological region of the hemispheres that we should definitely know in what sensory region of the cortex words are principally recalled to mind during ordinary thought-processes. Two distinct views radically opposed to one another have been advocated on this subject.

There is the view (1) that words are revived as "motor processes"—that is, as faint excitations of the processes occurring in motor centres during the articulation of words; and (2) there is the view that words are revived in ordinary thought in the main as auditory ideas or images. The former view has for a long period been promulgated by Hughlings Jackson, and has more recently received the strong support of Stricker, both of them regarding Broca's region as a motor rather than as a sensory centre. The latter view is that which the writer has now for many years advocated. The fundamental nature of my opposition to the former view may be gathered from the fact that I have for many years expressed the opinion that motor centres, wherever they may be situated, are parts whose activity appears to be wholly free from subjective concomitants. No "ideal" reproductions seem ever to take place in such centres; they are roused into activity by outgoing currents, and, so far as we have any evidence, the induction in them of molecular movements which immediately afterwards issue through cranial and spinal motor nerves to muscles are, like those which they engender, simply physical phenomena.[5] It is true that the altered condition of the muscles and of contiguous parts induced by these outgoing stimuli together engender a body of ingoing impressions, the terminus for which is the kinæsthetic centre. This latter is therefore a true sensory centre, and in it images of movements or "ideal movements" may be revived in a more or less vague manner as already indicated.

But, even if we adopt what appears to me to be the more legitimate view that articulatory movements as well as movements in general are represented in the cerebral cortex only by sensory centres, there are still, I think, good reasons for rejecting the notion that the "material of our recollection" in the use of words during silent thought is primarily revived as glosso-kinæsthetic impressions in Broca's centre. The principal reasons opposed to this view seem to me to be as follows. In the first place it must be evident from the mode in which speech is acquired by the child that during the few months in which words enter into the simple trains of thought, before he has acquired the power of articulating them for himself, they must be revived as

[4] "The Muscular Sense: its Nature and Cortical Localisation," Brain, April, 1887, and "On the Neutral Processes Underlying Attention and Volition," Brain, April, 1892.

Hosted by Google

auditory impressions. Secondly, there is, as we have seen, a much greater definiteness of impression and readiness of recall for auditory than for articulatory feelings; and so far, therefore, there is a greater fitness in the former for serving as the "material of our recollection" of words in ordinary thought processes. Thirdly, there is reason to believe that revived auditory feelings continue after the acquirement of speech by the child to have the same relation to his thought-processes as they must have had before his acquirement of the power of speaking. If this were not so it would be impossible to understand why total deafness supervening in a child in full possession of speech as late as the fifth, sixth, or even the seventh year, will certainly entail dumbness unless the child be drilled in lip-reading, that is, unless the primary incitation to acts of speech be gradually transferred from the auditory to the visual centres. Fourthly, because, as we shall subsequently find, there is much evidence against this view to be derived from the study of speech defects, and none that I am aware of telling unmistakeably in its favour.

It seems to me to be an error to attempt to settle such a question by endeavouring to ascertain which form of word-memory reveals itself most in consciousness; and I venture to think that the recent principal advocate of the view that words are primarily revived during silent thought as "motor processes," relies too much upon what is in reality an untrustworthy method—that of introspection. By concentrating his attention upon the genesis of his own speech, Professor Stricker inevitably brings its expressive side into undue prominence. As Taine says[6]: "Plus on imagine nettement et fortement une action, plus on est sur le point de la faire... quand l'image devient très lumineuse elle se change en impulsion motrice."[7]

The primary revival of words during thought takes place, I submit, in the great majority of persons by a subconscious process in the auditory centre, and tends to be immediately followed by correlated revivals in the glosso-kinæsthetic centre, and these again by incipient or complete activities in the bulbar motor centres. It may be perfectly true that kinæsthetic memories vary in intensity in different individuals, as do auditory and visual memories; and it might have been thought that Stricker and also Ballet (who adopts his view in a more discriminating manner) were to be counted as persons in whom the former kind of memory is highly developed, but for the fact that Ballet expressly states[8] his inability voluntarily to recall cheiro-kinæsthetic impressions. He believes, moreover, for reasons given, that the same holds good for Stricker. Thus they cannot voluntarily recall the kinæsthetic impressions associated with the act of writing a word, but they say they can recall the kinæsthetic impressions associated with the articulation of the same word, even although the movements in the latter case are much more of an automatic type. These apparently contradictory results are easily explicable in accordance with my views, when one considers how the thought of a word naturally runs on to an incipient articulation[9]; while, on the other hand, the mere thought of the same word has no appreciable tendency to evoke writing movements. The negative results of Ballet and Stricker with cheiro-kinæsthetic revivals of words would seem, therefore, to have all the force of a crucial experiment and to throw great doubt upon their supposed ability primarily to revive words in the glosso-kinæsthetic centre.

It seems pretty certain, therefore, that the real linguistic counters for thought are the auditory and visual memories of words. And in regard to these two I believe that in the very large majority of persons it is the auditory word-memory which is first revived in silent thought. This view is now very generally adopted, as may be seen by reference to the works of Ross[10] and Bernard.[11] It appears also to be the view of Herbert Spencer, since he says[12]: "Our intellectual operations are, indeed, mostly confined to the auditory feelings (as integrated into words) and the visual feelings (as integrated into ideas of objects, their relations and their motions)." Although the first stage in the revival of words seems to occur, however, in the auditory centre, the molecular disturbance thus initiated is immediately transmitted to a varying extent in two directions. It is transmitted to the visual word-centre on the one side and to the glosso-kinæsthetic centre on the other—to the latter strongly where the thought is to issue in speech, and to the former strongly where it is to issue in writing.

There can be no doubt that in some persons the visual centres as a whole are more highly developed and organised than the auditory centres, and *vice versâ*. The existence of such differences has been thoroughly shown by Francis Galton.[13] Thus he took steps to test the power of what he calls "visualising"—that is, the ability of persons to see with the mind's eye distinct images of objects in their natural grouping and colouring. The one hundred answers that he received as to the power possessed by the persons selected of visualising the breakfast table to which they had sat down in the morning disclosed an extraordinary range of variation in this respect. One of those who had the highest power of visual recall answers: "Thinking of the breakfast table this morning, all the objects in my mental picture are as bright as in the actual scene." One of those who had the lowest power answers: "No individual objects, only a general idea of a very uncertain kind." Galton adds: "There are a few persons in whom the visualising faculty is so low that they can mentally see neither numerals nor anything else; and again there are a few in whom it is so high as to give rise to hallucinations." In this general sense persons may well be classed as "visuals" and "auditives" respectively; and we may thus indicate for this or that person which is the more potent sensory endowment.[14]

Supposing, however, that a person is a "visual" in this general sense, it should not, in my opinion, be taken as necessarily implying that visual memories of words are for him the first to be revived in silent thought. If it were so we should expect to find speech greatly interfered with in many cases of simple word-blindness; but this seems comparatively rarely to be met with, the contrast in this respect being most striking between destruction of the visual and destruction of the auditory word-centres respectively. The primary revival of words may, perhaps, still occur in a visual in the auditory centre, only in such a person these primary revivals may be strongly backed up and reinforced by visual images. So that where the auditory word-centre is damaged in such a person its action, as a leader in the memorial recall of words, might to a certain extent be taken on by the visual word-centre; while in a person who is not a "visual" but little compensation of this kind could occur for the loss of the auditory word-centre. Thus the clinical effects in the form of speech disturbance would be different and altogether more marked in the latter case. It will be found that many recorded cases of speech defect lend support to these views, and that this, in fact, is the real practical outcome of all that has been said by Charcot and his followers as to the division of persons (in reference to the interpretation of speech defects) into four categories—"auditives," "visuals," "motors," and "indifferents"; a doctrine which has been fully set forth by Ballet.

I contend that this doctrine must not be taken to mean anything more than that the different kinds of word-memory referred to in the first three types may be met with in different degrees of excellence, and that in the fourth type there is no one kind of memory which is developed to a preponderating extent. In the latter class there would be no ground for supposing that the ordinary rule as to the primary revival of words taking place in the auditory centre is ever altered. As to the existence of persons representative of the third class I have already expressed my doubts—that is to say, I can find no good reasons or evidence to show that words ever arise in silent thought primarily in the kinæsthetic centres. I doubt whether these memories are capable of separate voluntary recall, and do not believe there is any evidence to show, as Bernard says,[15] that "the motor centre for speech may become independent of the sensorial centre which had presided over its education."

The case is altogether different in regard to individuals of the second class—the "visuals"—because not only does the power of memorial recall in the visual centre vary immensely

[9] Ballet, in fact, says, loc. cit., p. 52:—"Chez moi, comme chez la plupart des moteurs je pense, la parole intérieure devient souvent assez vive pour que j'arrive à prononcer à voix basse les mots que dit mon langage intérieur." What he says on the next page shows that he is not a strong "visual," but does not tell against his being a strong "auditive." His better memory of a lecture after delivering it might be explained by the help derived from auditory or kinæsthetic impressions of the words, or from the two in combination.

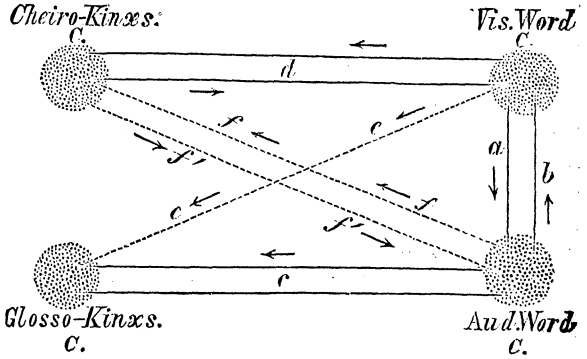
in different persons, as we have seen, but there is also good reason to believe that in a small minority of persons the primary revival of words during a process of silent thought may take place therein, just as it does in the act of reading. Thus Galton says[16]: "Some few persons see mentally in print every word that is uttered; they attend to the visual equivalent and not to the sound of the words, and they read them off usually as from a long imaginary strip of paper." It is possible, of course, that a person possessed of this high visualising power, whilst he may be thus aided in the delivery of a speech previously written, may nevertheless, in a process of silent thought, conform to the ordinary rule and revive words voluntarily in his auditory centre. But it may be otherwise with some few persons, so that, as Ribot supposes, they may habitually think and represent objects "by visual typographic images." Something of this kind we are bound to suppose must occur in a word-deaf person whose auditory word-centre is destroyed and who is yet able to speak—a rare conjunction that has occasionally been met with; just as we are bound to suppose that when a congenitally deaf and dumb child is taught to speak by the lip-reading process he brings this about by means of a primary revival of visual images, which act directly upon the glosso-kinæsthetic centre and thence upon the motor centres in the bulb.[17]

Bernard has cited[18] a remarkable instance of a patient who possessed a visual memory exceptionally strong, whilst his auditory memory was proportionally weak. In this patient the visual images of words and figures were evidently predominant during thought processes. "If he recited a lesson whilst at college, or an extract from a favourite author later on, two or three readings were sufficient to fix in his memory the page with its lines and its letters, and he recited by mentally reading the desired passage, which, at the first summons, presented itself with the greatest distinctness." Ballet[19] also quotes a letter from a librarian at Geneva which is extremely interesting. He writes: "When I think of a word or a phrase I see very distinctly this word or this phrase printed in ordinary characters, or written in my own writing or that of another person; the letters of a word are distinct from one another, and the intervals between each word written in black appear to me also. I see them in white. All my reproductions of words are visual." The same author mentions an orator, Hérault de Séchelles, who was accustomed, as it were, to read his speeches; and cites an epigram of Charma, also a "visual," who, speaking of the class to which he belongs, said, "Nous pensons notre écriture, comme nous écrivons notre pensée."

Undoubtedly, then, it would seem that there are certain exceptional persons who, as it were, read rather than hear their thoughts; and in whom, as Ballet says, the visual images of words acquire such an importance that they alone constitute the medium of their internal speech. Still, in spite of these exceptions, the general rule is that auditory images constitute the most potent representations of words, whilst visual images form the most potent representations of ordinary external objects.



THE REVIVAL OF WORDS FOR SPEECH IS A COMPLEX PROCESS

The views just expressed refer, as I have said, to the seat of the primary revival of words in memory, because there is strong reason for believing that the activity when once initiated does not limit itself to a single centre. It must be borne in mind that the structural relations existing between the different seats of word-memory and the modes in which these are functionally related is in accordance with what occurs in ordinary processes of perception. In regard to such a process I have elsewhere said[20]: "When any one constituent of a natural cluster of sensations comes within the range of the corresponding sense organs of an animal the other possible impressions composing the cluster (and representing the organism's knowledge of the external object) become simultaneously nascent in memory, so that the object is perceived or recognised. If in a dark room my hand comes upon an orange or a book, either of these sensations of touch will immediately fuse with nascent ideas of other possible sensations from the same object (whichever it may be), so that this object is perceived as a present external reality. ..... Thus it happens that an object is recognised immediately or intuitively, not so much by the mere single or double impression present, as by the blending of this with more or less fully revived memories of other impressions which have at various times been associated with the same object. Truly enough, as Bain says, 'When we see, hear, touch, or move, what comes before us is really more contributed by the mind itself than by the present object.' ..... It is therefore by the simultaneous consciousness and fusion, as it were, of the subjective side of various new and old impressions that a present object is perceived and recognised. It could only be by the previous establishment of structural communications between the severally related sensory cells (in different centres) that the excitation of those of any one order would suffice to revive more or less strongly in other groups just such molecular changes as like objects had on previous occasions excited. And it may be easily understood that the molecular movements initiated by any one or two sense impressions may start from such groups of cells and thence flow over into all communicating channels between them and the cells of other related groups."

In a similar manner it may be supposed that the revival of activity in the auditory centre during the voluntary recall of words does not remain limited to that centre, but gives rise, as I have already said, to molecular movements in two directions—that is, forwards to related portions of the kinæsthetic centre and backwards and upwards to related portions of the visual centre—though with different degrees of intensity in different persons.

It is of importance to remember that for ordinary persons (that is, for those who are neither congenitally blind nor congenitally deaf) the four memories of words seem to be mainly called into play in definite couples—namely, the auditory and the glosso-kinæsthetic revivals taking place during articulate speech, and the visual and cheiro-kinæsthetic revivals taking place during ordinary writing. By this I mean that in expressing one's self in spoken words memories of such words are first principally revived in the auditory centre, and that the nerve units thus called into activity immediately rouse through commissural fibres (see Fig. 2, *c*) the corresponding glosso-kinæsthetic elements before the pronunciation of the word can be effected through the aid of the motor centres in the bulb. Probably in a healthy brain there is some amount of concurrent activity during speech in related portions of the visual word centre.

FIG. 2.

A diagram illustrating the relative positions of the different word-centres and the mode in which they are connected by commissures. The connexions indicated by dotted lines indicate possible but less habitual routes for the passage of stimuli.

Again, when we are expressing our thoughts by writing, though the memories of the words are probably first revived in the auditory word-centre, corresponding memories are almost simultaneously revived (through the intervention of the audito-visual commissure, *b*) in related parts

[16] Loc. cit., p. 96.

[17] In the case of a deaf and dumb child taught to speak and understand others by means of hand and finger movements their thought-counters would be combined visual and kinæsthetic impressions, or in the case of one who had been taught to read much from early life they might be "visual typographic images." On the other hand, in the case of a congenitally blind person who has been taught to read aloud by means of raised letters and words excitation of the centres for touch and kinæsthesis would constitute the initial processes in the act of reading aloud, although revived auditory impressions might constitute, as in ordinary persons, the habitual thought-counters. A patient of the former class whose history has been reported by E. Fournier (Essai de Psychologie, Part II., chap. v.) says: "Je sens quand je pense que mes doigts agissent, bien qu'ils soient immobiles. Je vois intérieurement l'image que produit le mouvement de mes doigts."

of the visual word-centre, and from this region stimuli pass by another commissure (*d*) to corresponding cheiro-kinæsthetic elements before the actual writing of the words can be effected through the instrumentality of motor centres in the cervical and upper dorsal regions of the spinal cord.

There can be no doubt, in fact, that the functional association existing between the auditory and the glosso-kinæsthetic centres, as well as that between the visual and the cheiro-kinæsthetic centres, is of the closest kind. No less intimate, however, is the bond of association between the activity of the auditory and the visual word-centres themselves. These latter centres are often necessarily called into associated activity in immediately successive units of time. This happens, for instance, in two such common processes as reading aloud and writing from dictation.

In reading aloud the primarily excited visual word-centre must arouse, through (*a*) the visuo-auditory commissure, related parts of the auditory word-centre, since this is the part which ordinarily calls the glosso-kinæsthetic centre into activity, whence properly coördinated incitations issue from the cortex, in order to call into play the motor centres in the bulb.

Again, in writing from dictation the sounds of the words reach the auditory word-centre, and the activity thus aroused becomes transmitted through (*b*) the audito-visual commissure to related parts of the visual word-centre, this being the part that usually rouses the cheiro-kinæsthetic centre into activity, whence properly coördinated incitations issue from the cortex in order to call into play the motor centres in the cord concerned with the act of writing.

In exceptional cases it seems that the ordinary functional coupling of the auditory with the glosso-kinæsthetic and of the visual with the cheiro-kinæsthetic word-centres is not adhered to. Thus the deaf-mute thinks in the main with revived visual symbols (either of hand or of lip movements) and it is from the organic seats of these that incitations pass to related parts of the glosso-kinæsthetic centre (*e*, *e*). A similar stimulation of these centres direct from the visual word-centre seems occasionally to obtain in persons who are not deaf-mutes. We have already assumed it to be possible for some few "visuals," and subsequently for the interpretation of certain cases of disease in which the auditory word-centre has been damaged we shall find ourselves obliged to have resort to such a supposition.

Again, in those children who have been born blind, but have nevertheless ultimately learned to write, a direct association must become established between the auditory and the cheiro-kinæsthetic word-centres (*f*, *f*). The same kind of associated activity between these two centres must exist in certain other persons not born blind, seeing that some patients suffering from word-blindness owing to destruction of the visual word-centre are able, nevertheless, to write, either spontaneously or from dictation.

This functional unification of the word-centres of which I have been speaking does not, however, remain in a state of isolation. Words that are heard are first of all associated in the mind of the child with external objects, so that such auditory impressions become linked, by means of associational fibres, with the organic seats of the several sensory impressions—also freely connected with one another—that the child has been able to derive from this or that object. Thus the name subsequently becomes revived as part of the perceptive process whenever the object is again presented. The sight of the mother recalls the name "Mamma," just as the sound of this word would revive the corresponding visual, tactile, and other images. After a time the auditory representative of the name becomes reinforced by glosso-kinæsthetic impressions as soon as the child learns to utter the word; later by visual impressions, when it learns to read, and by cheiro-kinæsthetic impressions when it has learned to write.

The several components of word-percepts are thus brought, not only into relation with one another, but become no less intimately associated with the several sensory components of object-percepts. The result is that the hearing or the sight of the name of any object immediately calls up in the older child or in the adult an idea of the object, just as its presentation to sight or other sense produces a nascent activity in the several centres in which its name is registered, though mainly in the auditory and the visual centres.

Words soon become to a very large extent the symbols whereby we carry on our thoughts, and this thinking by means of words becomes all the more thorough as though's become more complex. We can think of a particular person or of a particular plant as well by recalling the visual image as by recalling the name. But when in thinking we have to recall general names, such as "animal" or "tree," or still more abstract names such as "virtue" or "vice," it becomes certain that in silent thought we use the words as symbols for the more or less complex ideas which they represent. And if we bear in mind that the seats in which these words are registered (our word-centres) are in organic and functional relation with the seats of registration of the corresponding percepts, concepts, &c., we are enabled in a measure to understand how the revival of the word in the mind (as the thought-counter) is associated with an almost simultaneous activity in the seats of registration of the corresponding percepts and concepts.

We may thus recognise how it happens that in simple acts of perception, and still more in simple thought processes, we have no limitation of cerebral activity to narrowly localised centres, but rather widespread processes of activity in very varied regions of the cortex, and that, too, in both hemispheres of the brain. In our talk about individual centres and their functions we are apt to forget how much the brain acts as a whole even in operations that seem comparatively simple, and many of those who have written on aphasia have, as I venture to think, not sufficiently taken into account the fact that the name constitutes an integral element of the percept or of the concept.

On the Different Modes of Excitation of the Word-centres, and on the Reason of their Functional Predominance in the Left Hemisphere.

It is important to recollect that word-centres are naturally called into activity in states of health in three modes, but that failure in the possibility of their excitation by one or other of these modes occurs in various morbid conditions, leading to this or that kind of speech defect. The three modes of excitation are these: (1) By means of "sensory" impressions coming from without; (2) by "association"—that is, by impulses communicated from another centre during some act of perception or thought process; and (3) by "voluntary" recall of past impressions, as in an act of recollection. It is convenient for practical purposes to separate these second and third modes of calling into activity the perceptive centres; still they are probably closely related to one another and scarcely separable in nature, although the associational processes in the case of "volitional" excitation may be so difficult to trace that the recall assumes a quasi-spontaneous character.

The excitability of the centres—that is, the molecular mobility of their nervous elements—may vary with age, state of health, or the existence of different morbid conditions. Their excitability may be so much lowered that they are only capable of responding to powerful stimuli; so that while volitional recall (or "recollection") may be impossible within their province, such centres may still be capable of acting in "association" with others—that is, in an automatic manner during an ordinary process of thought—or at least under the "sensory" stimulus which initiates a perceptive process. At other times the excitability of the perceptive centres may be unduly exalted, so as to lead to hallucinations, illusions, and a wholly different class of defects such as are often met with among the insane.

From what has been said in a previous section it will be seen that I entertain doubts whether kinæsthetic word-memories of either kind are capable of being revived alone in a voluntary manner.

As to the causes which have determined the greater or almost exclusive influence of the left hemisphere in inciting speech movements, and therefore in acting upon the bulbar motor centres for words, only conjectures can be offered. It is, however, now pretty generally agreed that the immediate or proximate cause is to be found in the fact of the predominant use of the right hand, which entails a greater functional activity upon the left cerebral hemisphere. This view rests principally upon the now ascertained fact that in the great majority of cases in which aphasia has occurred as a result of brain lesions in the right hemisphere (with or without the association of left hemiplegia) those so affected have been left-handed persons.[21] It would thus seem to

[21] According to Seguin, out of 266 cases of aphasia he found 243 with right and 17 with left hemiplegia; that is, somewhere about 6 per cent. W. Ogle, on the other hand, from inquiries among 2000 hospital patients, found that 85 of them were left-handed; that is, about 4¼ per cent.

Hosted by Google

follow that the predominant use of the right hand or of the left hand carries with it, as one of its associated effects, the leading activity in the production of speech by the left or the right hemisphere respectively; and that we must consequently push our question further back, and inquire as to the causes that have led to this predominant use of the right hand.

This problem has been considered by Pye-Smith,[22] and also in a more exhaustive manner by William Ogle,[23] but can only be briefly alluded to here. It has been thought to depend largely upon tribal or social customs and early tuition of young children by their mothers, though doubt has been thrown upon these views as giving any adequate explanation of the problem. William Ogle looks rather to certain peculiarities in the mode of origin of the left and right carotids respectively as calculated to favour a slightly freer blood supply to the left cerebral hemisphere. If this were really so, it is conceivable that it might after a time have led to a slightly earlier development of the convolutions on the left side of the brain (which has been affirmed to occur by Gratiolet, though denied by Carl Vogt and Ecker), and thus perhaps have led to a preferential use of the right hand in the early and more definite movements of the child. Such preferential use being once started and maintained through several generations, it is only to be expected that it would continue; for if the effects of use and disuse are inherited as, with Herbert Spencer, I believe to be the case (in spite of all that Weismann says to the contrary) heredity would coöperate with the original cause in confirming and making general this preferential use of the right hand.

But whatever may have been the original cause of this now very general attribute of right-handedness—and the chief difficulties of the problem with which we are concerned lie here—it would easily follow that with its continuance in process of time the left hemisphere should become (as it has been found to be) slightly heavier than the right, and that the left carotid might become (as it is said to be) very slightly larger than the right carotid. It is practically certain that the great preponderance of right-hand movements in ordinary individuals must tend to produce a more complex organisation of the left than of the right hemisphere. We may confidently look for the existence in it of the organic basis of a vastly greater and more complex tactile experience; and as movements of the right hand and arm are more frequent, both as associated factors of this experience and in other ways, we have also a right to suppose that the kinæsthetic centres will be similarly developed to a notably greater degree in the left hemisphere.

Many years ago I ascertained a fact which then seemed very difficult to understand—namely, that the specific gravity of the cortical grey matter of the brain in the left frontal, parietal, and occipital regions is often distinctly, though slightly, higher than that from corresponding regions of the right hemisphere. Full details as to this will be found in a paper "On the Specific Gravity of the Human Brain," published in 1866.[24] Now such an increase in specific gravity might easily be produced by the greater number of cells and associational fibres which the extra sensory and derivative functions above referred to would necessarily entail.

Thus it may, in brief, be said that this preponderating activity of the left hemisphere in regard to tactile and kinæsthetic impressions (about which there is no room for doubt) may have much to do with the fact that the left hemisphere is the more potent and seems to take the lead in some thought processes, as well as in giving rise to the voluntary excitations which determine the muscular acts involved in articulate speech. A greater convolutional complexity of the lower part of the left frontal lobe as compared with the right, which has been found to exist, is thought to be a result of this preponderant activity of the left hemisphere in the production of articulate speech. Some evidence in favour of this view is to be found in the fact that Broadbent, in his examination of two brains taken from left-handed persons that were submitted to him by William Ogle, found in them the reverse condition—that is, that the greater convolutional complexity was on the right rather than on the left anterior lobe.[25]

There still remains the question why one cerebral hemisphere only should be efficiently educated for the perception of speech and for the production of speech movements, when, seeing that the bulbar motor centres are bilateral, it might seem that such centres would be likely to receive their stimuli from both hemispheres. In partial reply to this question Moxon, in a very able paper,[26] long ago suggested that the call upon attention was so great for the production of the extremely elaborate movements concerned in speech that the necessary concentration of attention would be much facilitated if this process of education were limited to one hemisphere. Whatever may be thought of this ingenious suggestion, nothing better has hitherto been forthcoming.[27]

What has just been said as to the action of the left hemisphere rather than the right in the production of speech must be understood with certain reservations. It must not be supposed that the right hemisphere remains entirely uneducated, either in regard to the comprehension or to the production of speech. Little is said by writers generally on this subject, and what has been said has reference principally to the third frontal convolution. A hypothesis as to the functions of this part of the brain has been enunciated by Hughlings Jackson,[28] and another view, as to what is figuratively termed the "overflow of education into the opposite hemisphere," has been expressed by Wyllie.[29] But neither of these hypotheses appears to me to be in accord with existing knowledge.

The most important points to be borne in mind in reference to this subject would seem to be these. All the movements concerned in speech are movements produced by symmetrically placed muscles on the two sides of the body; there is just as much reason, therefore, for the registration of kinæsthetic impressions resulting from speech movements in the right as in the left third frontal convolution. Again, it cannot be supposed that auditory impressions from spoken words do not pass from each ear to similar regions in the opposite cerebral hemisphere; and our present knowledge makes it equally improbable that the visual impressions of words are not registered in a visual word-centre in each hemisphere. For each of these three sets of afferent impressions, therefore, there is, as I believe, no question of an "overflow" from one to the opposite hemisphere; on the contrary, each hemisphere receives its own proper share of ingoing impressions, and doubtless registers them in a more or less similar fashion. That this should be so seems an obvious truth, though it is one that hitherto appears to have been very imperfectly realised. Again, it may be taken as established, for reasons which will subsequently appear, that the separate centres composing each of these pairs are brought into functional union by means of commissural fibres forming part of the corpus callosum. So far, therefore, we seem bound to admit that each hemisphere has the chance of being equally educated, so far as the mere *reception* of speech impressions is concerned.

It is, however, when we come to the executive side of speech functions that the great difference begins to appear between the relative activity of the two hemishperes of the brain. For reasons which we have previously been dimly endeavouring to indicate, the executive speech functions become relegated to one hemisphere, and this leading hemisphere, generally the left, becomes for this and for the other reasons which we have adduced more highly organised. The fact that the volitional impulses for the incitation of speech pass off from this hemisphere leads of necessity to the gradual perfecting of the associational channels between the auditory and the glosso-kinæsthetic centres, as well as between the auditory and the visual word-centres of the left hemisphere, and also to the perfecting of

Left-handedness, curiously enough, was found to be "twice as common in men as in women." Ogle shows, too, how very frequently there is hereditary transmission of this peculiarity.

[27] Moxon's paper is, indeed, in other respects remarkable, looking to the date at which it was written. Thus he speaks of spoken words as represented in Broca's region by "educated associations of movements"; and the meaning that he attaches to this phrase is rendered evident further on when he dwells upon the "inconceivable pitch of education which is given to these supra-motory departments, if I may so call them, of the brain, which hold ready for use the memorial forms of outgoing words," or still better where he says, "The situation of the ideas of *associated motions* which form the faculty of speech is supra-motory, whilst the situation of the ideas of *associated sensations* which form the faculty of language comprehension is supra-sensory."

Hosted by Google

the outgoing channels of communication between these sensory centres and the true motor centres in the bulb. The corresponding associational and outgoing channels in the opposite hemisphere, however, being but little used, may remain comparatively undeveloped.

This difference in the degree of activity of the two cerebral hemispheres during speech would tend to become more and more accentuated in future years, and would in all probability lead to a much higher grade of functional activity, even on the receptive side, in the three kinds of word-centres pertaining to the leading hemisphere.

Views of this kind as to the partial education of the word-centres of the opposite hemisphere will be found to be of considerable importance when we come to speak of the modes in which destruction of one or other of the word-centres in the leading hemisphere may be compensated—or, in other words, of the way in which a cure may be brought about in this or that form of speech defect.

DOES CONCEPTION TAKE PLACE IN A CENTRE ALTOGETHER APART FROM PERCEPTION?

The first authoritative writer on defects of speech who started the notion of the existence of an altogether separate centre for conception or ideation was Broadbent. This he did in a very important memoir, "On the Cerebral Mechanism of Speech and Thought," published in 1872.[30] Whilst there adopting some views which I had previously published on the subject of the cerebral processes that occur in perception,[31] he made a departure from them in the direction above indicated. The functions that I spoke of as being carried on in the perceptive centres he divided into two stages. He said: "There is a primary or rudimentary perceptive act in which the external cause of a given set of sensations is recognised as such, and in which the simple attributes, as of form, colour, hardness, &c., are perceived. And there is a higher degree of elaboration in which, by the combination or fusion of perceptions derived from the various organs of sense, a conception or idea of an object as a whole is obtained. This is a new and distinct process, and is usually accompanied by the affixing of a name to the object. To the 'perceptive centres' I relegate simply the translation of sensations into rudimentary or primary perceptions, and these centres must lie somewhere in the marginal convolutions which receive radiating fibres from the crus and central ganglia, upon which therefore impressions will first impinge, and which are symmetrically combined by the fibres of the corpus callosum. The higher elaboration, the fusion of various perceptions together, and the evolution of an idea out of them, will be accomplished not by radiation from one perceptive centre to all the others, but by convergence of impressions from the various perceptive centres upon a common intermediate cell area, in which a process analogous to the translation of an impression into a sensation and of a sensation into a primary perception will take place. This intermediate cell area will form a part of the supreme centre, and will be situated in the superadded convolutions which receive no radiating fibres."

In a subsequent communication some years later these views were still further developed by Broadbent.[32] The centre for concepts was then termed the "naming centre," whilst a related higher motor centre was postulated as a "propositionising centre," in which words other than nouns were supposed to be registered, and where sentences were formulated preparatory to their utterance through the instrumentality of Broca's centre.

This supposed convergence of impressions from the various perceptive centres into a new region in which "conception" and "naming" take place is a view totally different from my own, which nearly thirty years ago was thus expressed:[33] "In the perceptive centres the primary impressions made upon the organs of sense are converted into 'perceptions proper'—that is to say, they receive their intellectual elaboration, and this elaboration implies an intimate cell and fibre communication between each perceptive centre and every other perceptive centre, since one of the principal features of a perceptive act is that it tends to associate, as it were, into one state of consciousness much of the knowledge which has been derived at different times and in different ways concerning any particular object of perception. An impression of an object, therefore, made on any single sense centre on reaching the cerebral hemispheres, though it strikes first upon the perceptive centre corresponding, immediately radiates to other perceptive centres, there to strike upon functionally related cells, all this taking place with such rapidity that the several excitations are practically simultaneous so that the combined effects are fused into one single perceptive act."[34] Thus the work which Broadbent supposes to be done in his "naming" or "concept" centre is according to my view carried out by the simultaneous activity of the different perceptive centres, and certain annexes which are derivative developments therefrom, of which I shall subsequently speak. And, again, I have postulated, instead of a single separate "naming centre," the existence of four "word-centres" as important and intimately correlated parts of the more general auditory, visual, and kinæsthetic centres.

Consequently I never seek to explain certain cases of speech defect, as he and others whom I am about to mention not unfrequently do, by supposing the existence of lesions in a localised centre for "concepts," or of lesions involving the commissural fibres proceeding to or issuing from such a centre.

With variations in detail, views similar to those of Broadbent as to the existence of a special centre for concepts were subsequently published by Kussmaul[35] and Charcot,[36] whilst the views of the latter were adopted and further promulgated by Bernard[37] and Ballet.[38] The existence of a separate centre for concepts is also postulated by Grasset.[39]

The views of Kussmaul were embodied in an elaborate and complicated diagram which it is unnecessary to describe. A more simple and easily to be comprehended diagram was also produced by Charcot (and is to be found in the work of Bernard), which is based upon the same principles as the scheme issued by Broadbent, with the exception that he omits the "propositionising centre" and also adopts my view as to the existence of separate word-centres. He, however, makes the several sensory impressions converge to an "ideational centre" in order that their meaning should be realised, and indicates that the speech centre (that of Broca) and the centre for writing movements (both of them as "motor" centres) are called into activity directly from this ideational centre, as well as from the auditory and the visual centres respectively.

Some diagrams that have attracted much attention were also published by Lichtheim in illustration of his well-known paper on aphasia.[40] They likewise show a centre for concepts altogether apart from the sensory centres, and in his endeavours to explain the different kinds of speech defect he refers two of his types to a destruction of supposed afferent and efferent fibres proceeding to and from this conceptual centre. While, therefore, his diagrams and his language in many parts of his paper would make one think that he adopted in full the view as to the existence of a wholly separate centre for concepts, he says towards the end of his paper[41] "this has been done for simplicity's sake," and that he does not "consider the function to be localised in one spot of the brain, but rather to result from the combined action of the whole sensory sphere." This statement, though it is quite in accordance with my own view, seems to me to invalidate much of his exposition and to make it almost impossible for him legitimately to suppose, as he does, that two of his types of speech defect are to be explained by the supposition of the existence of a lesion involving either the afferent or the efferent fibres pertaining to such a widely diffused centre. In addition there is the serious defect that his diagrams are at variance with his views on this important subject.[42]

My dissent from these particular views of Broadbent

[34] From this it is evident that there can in reality be only one perceptive centre, although its different component parts were formerly by myself (as well as by Broadbent) spoken of as "perceptive centres" because their functional activities were integral components of a perceptive act. I recognise now that it would have been better not to have used this term as a name for these centres—that they are, in fact, more appropriately spoken of as sensory centres.

was expressed in 1880,[43] and again more strongly against them as well as against the allied views of Kussmaul, Charcot, and Lichtheim, in 1887.[44] I am glad to say that this dissent from these doctrines has been followed by that of A. de Watteville,[45] Ross,[46] Allen Starr,[47] and Wyllie,[48] all of whom have likewise decided against the propriety of postulating the existence of a separate centre for ideas or concepts.

My opposition to this postulation of a separate "centre for concepts" was based originally upon psychological considerations. It seemed to me wholly unnecessary and at variance with what appeared to be the real nature of the process of perception.

Then, again, I am unable to find any clear evidence from clinical data tending to prove the existence of a separate "centre for concepts"—or, in other words, any existing forms of speech defect that can only be explained by supposing the existence of a lesion in such a centre or in the course of its afferent or efferent fibres. I am convinced that the supposed necessity for assuming the existence of a "centre for concepts," when seeking to interpret different forms of speech defect, may in many cases be obviated by a fuller recognition of the different degrees of functional excitability that may obtain in the auditory and the visual word-centres respectively. We shall see that their molecular mobility may be so much lowered that they are only capable of responding to powerful stimuli. Thus, whilst volitional recall or recollection may be impossible within their province, they may still be capable of acting in association with other centres—as when reading may be fluent though voluntary speech is greatly impaired; and still more easily under a direct sensory stimulus—as when a word is repeated which the patient has just heard pronounced.[49]

Another cause that has led to this postulation of a "centre for concepts" is traceable, I think, to an inadequate realisation of the nature of a perceptive process and of the fact that a name may and does constitute an integral part of the complexus of revived sensory impressions which go to constitute such a process.

Again, as it would be quite easy to show, perceptive processes vary greatly in complexity and merge by insensible gradations into processes of conception. It seems thoroughly legitimate, therefore, to suppose that these latter more specialised modes of mental activity, whilst having their roots in perceptive centres, must be completed in outgrowths therefrom—that is, in parts of the brain which are in close relation structurally and functionally with the several sensory centres. I have commonly spoken of such regions as "annexes" of the perceptive centres.

Of late Flechsig has called special attention to four areas of the cortex that differ from the sensory areas, since they are neither in relation with afferent nor with efferent fibres. He assumes[50] that these regions subserve higher mental functions than those carried on in the sensory centres, and terms such regions "association areas." These regions seem, therefore, to correspond with what I have referred to above as "annexes of the perceptive centres." They occupy a large proportion of the cerebral cortex, and are thus located by Flechsig: (1) in parts of the pre-frontal lobes; (2) a large portion of the temporal lobes; (3) a considerable area in the posterior parietal region; and (4) the island of Reil. These four fairly well-defined areas are, as above stated, not directly connected with afferent or with efferent fibres, and in addition to this two other reasons are given for supposing them to be concerned with the carrying on of higher functions. Flechsig points out, in the first place, that these regions remain immature and completely devoid of myeline for several months after birth, though the sensorial centres have arrived at comparative maturity; and, secondly, that these association centres are the parts which are especially developed in the brain of man as compared with that of the lower animals.[51]

It is only fair to Broadbent to point out that more than twenty years previously he had cited almost exactly these regions of the cerebral cortex as parts that were neither in direct relation with peduncular fibres nor with those of the corpus callosum, and that he had attributed to these regions just the same functions as those now assigned to them by Flechsig.[52] He adds: "Now the convolutions which I have enumerated as having no direct communication with the crus, central ganglia, or corpus callosum are, in the first place, those which are latest in order of development, and on this ground alone might be supposed to be concerned in the more strictly mental faculties which are latest in their manifestations. They are those which constitute the difference between the human cerebrum and the cerebrum of the quadrumana; and it would, moreover, seem to accord with the general plan of construction of the nervous system and with what we know of the mental operations that these convolutions, which are withdrawn, so to speak, from direct relation with the outer world, should be the seat of the more purely intellectual operations."

It is, I think, perfectly legitimate to suppose that the annexes of the sensory centres, to which I have previously referred, tend to be developed in the directions above indicated by Broadbent and Flechsig, though how much of these territories they occupy must remain altogether uncertain. It seems also probable that there is no sharp line of demarcation between these annexes and the several sensory areas, and that *the combined sensory areas together with the annexes are accustomed to be thrown into functional activity more or less simultaneously*. Thus the processes of perception and conception, together with revival of linguistic symbols, are probably almost as inseparable in their localisation as they are in their nature and modes of occurrence, and their anatomical substrata must be supposed to occupy a very considerable extent of the cortex of both hemispheres.

A final question now remains for consideration related to this other which we have just been considering. It is this—Where are we to look for the registration and revival of words in the cerebral cortex? It may be said that this question has been already answered. And so it has tentatively and in a general sense. We have laid stress upon the existence of four different kinds of memorial registration of words and the probable sites of such word-centres in the hemispheres. We have indicated also that the glosso- and the cheiro-kinæsthetic centres constitute definite parts of the general kinæsthetic centres, and that the auditory and the visual word-centres probably also constitute more or less separate parts of the general auditory and visual centres.

Something additional, however, may now be said concerning the sites of these word-centres which could not well have been said at an earlier period, and that is that each of them is probably to be found partly on the confines of its percept centre and partly on that of its related annexe. This supposition is made because some words (especially names of things, persons, and places) are in closest relation with sensory centres; whilst others, such as verbs, adjectives, prepositions, and other parts of speech constituting the framework of language, are in closer relation with conceptual processes. These two modes of functional activity are, as I have said, absolutely inseparable from one another, and therefore the several word-centres must be in most intimate relation both with the sensory centres and with their annexes.

If the views above expressed be anything like an approximation to the truth, it may be judged how vain it would be to attempt to base our explanation of any of the different kinds of speech defect upon the supposed existence of some one separate centre for "ideation," "conception," or "naming" which is connected by means of commissures (long enough and separate enough to permit of isolated damage) with sensory centres on the one side and with motor centres on the other. I am pleased to find that the views at which I have arrived on this important subject—while they differ so much from those held by some of the most authoritative writers on speech defects—are nevertheless in very close accord with those formed by one very distinguished writer and thinker on these subjects—viz., the

[48] The Disorders of Speech, 1894, pp. 230 and 235. Wyllie, however, I think, tends to convey an erroneous impression by representing in a diagram on p. 276 of his work the seats of word revival in a lower plane and of percept revival in a higher plane, and assuming that the stimulation of Broca's centre takes place from the seat of percept revival rather than from the auditory word-centre. This seems to be also the position of Lichtheim, judging from his Fig. 7 and what he says in reference thereto, loc. cit., p. 477.

[49] Examples will be given later when speaking of the defects due to disabilities in the auditory word-centre.

late Dr. James Ross. Thus, in his work "On Aphasia," he gave expression to the following views (page 125) :—"And on passing from thinking by percepts to thinking by concepts, and from that to thinking by abstracts, there are no new centres introduced, but only a complication upon complication of the one perceptive centre. All that can be said is that the correlative of perceptive thinking is excitation of that portion of the cortex of the brain which is directly connected with the sensory inlets; of conceptive thinking, excitation of portions of the cortex which are indirectly connected with them; and of abstract thinking, excitation of portions which are still more remotely connected with them. It must, however, be remembered that the effective working of the portions of the cortex which are remotely connected with the sensory inlets will in a great measure depend upon the integrity of those that are in direct relation with them. ..... Let us now attend to the effects of dissolution of this structure. A destructive lesion of the portions of the cortex which are most remotely connected with the sensory inlets would destroy the capacity of the patient for highly abstract reasoning, and would no doubt inflict considerable damage on the language in which abstract thought is embodied, but this condition would not be recognised as an aphasia; and even the intermediate portions of the cortex in which conceptive thought is carried on might be seriously damaged without giving rise to a special speech disorder, inasmuch as any impairment of speech which might be present would only be regarded as a part of a general decay of the reasoning faculties. When, however, the lesion is situated in or near to the sensory inlets a disorder of language results which is out of all proportion to the general impairment of the reasoning faculties." All that has been set forth above is thoroughly in harmony with the dictum of Max Müller, who says: "Though sensations, percepts, and concepts may be distinguished, they are within our mind one and indivisible. We can never know sensations except as percepts, we can never know of percepts except as incipient concepts."

The Goulstonian Lectures

ON

THE CHEMISTRY AND PATHOLOGY OF GOUT.

Delivered before the Royal College of Physicians of London,

BY ARTHUR P. LUFF, M.D., B.Sc, F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS IN ST. MARY'S HOSPITAL, AND LECTURER ON FORENSIC MEDICINE IN ST. MARY'S HOSPITAL MEDICAL SCHOOL.

LECTURE II.[1]

Delivered on March 25th.

THE SOURCES AND FORMATION OF URIC ACID IN PATHOLOGICAL CONDITIONS OTHER THAN GOUT IN WHICH IT APPEARS IN THE BLOOD.

MR. PRESIDENT AND GENTLEMEN,—Although I hold the opinion that in health uric acid is only formed in the kidneys, and that the uric acid found in the blood in gout is absorbed from the kidneys after formation in those organs, yet it must be borne in mind that there are other diseases besides gout in which uric acid appears in the blood, and in connexion with which it has most probably *not* been absorbed from the kidneys, but has been formed elsewhere in the system. I will therefore briefly consider what these pathological conditions are and what are the probable sources of the uric acid in such conditions. The investigations of von Jaksch, Klemperer, and others have conclusively established that the presence of uric acid in the blood is not a pathognomonic sign of gout, and also that uric acid may appear in quantities in the blood and be eliminated without causing gout.

Blood disorders accompanied by the presence of uric acid in the blood.—Von Jaksch[2] found uric acid in the blood in cases of both primary and secondary anæmia, pernicious anæmia, and splenic tumour. He also found it in the blood in conditions inducing dyspnœa—notably in heart disease, pleurisy with effusion, pulmonary catarrh, pneumonia, and emphysema. Klemperer[3] has recently confirmed the results of von Jaksch and others as to the presence of uric acid in the blood in leucocythæmia, and many observations have been made of the increased excretion of uric acid that accompanies this disease. Laache[4] found a daily excretion of 3·7 grammes (nearly six times the average normal amount) in a patient suffering from this disease. Bartels[5] observed a daily excretion of 4 grammes (more than six times the average normal amount). Stadthagen[6] found a daily excretion of 2 grammes (three times the average normal amount). Bohland and Scherz[7] found a daily excretion of 1·4 grammes (twice the average normal amount). Von Jaksch[8] concluded that the occurrence of uric acid in the blood was due to diminution of the oxidising activity of the red corpuscles and to consequent storing up in the blood of the uric acid formed in the body, which, according to his view, is normally oxidised and destroyed. Horbaczewski's view, which will be considered later, that the formation of uric acid is due to the disintegration of leucocytes, would equally apply, since in all the diseases in which von Jaksch found uric acid in the blood leucocytosis was present. Moreover, there is no experimental proof to support the view that uric acid is oxidised and destroyed by oxygenated blood; on the contrary, there is experimental proof that the process of oxygenation can, in the presence of nuclein, produce uric acid instead of destroying it.

Renal diseases accompanied by the presence of uric acid in the blood.—Von Jaksch[9] found uric acid in the blood in all the cases of renal disease that he examined, the proportions being especially large in cases of granular kidney disease and uræmia. Von Jaksch's results were confirmed by Klemperer,[10] who examined the blood in cases of contracted kidney and found uric acid always present.

Lead poisoning accompanied by the presence of uric acid in the blood.—Sir Alfred Garrod[11] examined the blood of nine patients suffering from plumbism and who had never suffered from gout, and found appreciable quantities of uric acid in the blood of seven out of the nine. Dr. Oliver[12] refers to the early stage at which anæmia becomes a prominent symptom of lead poisoning. Although no doubt the kidney mischief which occurs in connexion with plumbism is responsible for the appearance of most of the uric acid in the blood by interfering with its excretion by the kidney cells, yet it is possible that a small amount of the uric acid may result from the slight leucocytosis accompanying the anæmia of plumbism.

Fevers and absence of uric acid in the blood.—Von Jaksch found no uric acid in the blood of patients suffering from typhoid fever, intermittent fever, and acute rheumatism, nor in connexion with diseases of the liver, stomach, and intestines, when unaccompanied by anæmia. His observations seem undoubtedly to prove that the presence of uric acid in the blood is not a factor in the production of the so-called uric acid intoxication of fever. Fever, indeed, appears to influence unfavourably the production of uric acid. It is evident that in connexion with certain diseases, especially those in which leucocytosis occurs, uric acid may be present in quantities in the blood and yet not give rise to gout. The reason, in my opinion, is that in such diseases the kidneys being in a sound condition can readily eliminate the uric acid. A proposition that I wish to put forward is that the seat or site of formation of uric acid is a different one in gout to what it is in those blood diseases and disorders in which uric acid occurs in the blood without the development of gout. In gout I believe that all the uric acid present in the blood is absorbed from the kidneys owing to some affection of those organs—functional or organic—which interferes with the proper excretion of the uric acid manufactured in the kidneys. In cases of contracted granular kidney disease and in cases of plumbism the uric acid present in the blood is, I believe, derived from

the same source—viz., from the damaged kidneys. In blood diseases and disorders the uric acid present in the blood is probably derived from the nuclein of the leucocytes, and as the kidneys are in a sound condition it is readily excreted by them.

An interesting question that I will now consider is whether gout ever occurs without preceding kidney mischief of some kind or other; that is, whether if the kidneys remain sound it is possible for such an accumulation of uric acid to occur in the system as to produce an attack of gout. We will first ascertain whether there is any evidence that an affection of the kidneys (functional or organic) is associated with or precedes gout.

ASSOCIATION OF KIDNEY AFFECTIONS WITH GOUT.

In the first place I think that the old idea must be abandoned that the kidneys can only eliminate a certain amount of uric acid. That the healthy kidneys are capable of separating from the blood and excreting large quantities of uric acid is shown by the observations, previously referred to, of Laache, Bartels, Stadthagen, and Bohland and Scherz on the excretion of uric acid in cases of leucocythæmia. In this disease the blood is laden with uric acid, and all these observers found a greatly increased daily excretion of uric acid, varying from twice to over six times the normal amount. This large excretion of uric acid by the kidneys shows that urates do not themselves cause damage to the uric acid secreting cells of the kidneys.

Views as to the association of gout and kidney disease.—Sir Alfred Garrod, Sir William Roberts, and Levison all attribute the accumulation of uric acid in the blood of gouty persons to deficient excretion rather than to increased production. Sir Alfred Garrod holds the view that among the causes exciting a gouty fit is a functional failure of eliminating power for uric acid on the part of the kidneys. He also considers that this early functional failure is followed in cases of chronic gout by structural kidney disease. His view is that the uric acid present in the blood in gout is formed in the kidneys and is absorbed from them into the blood. This view is quite compatible with the theory that a defective capacity of the kidneys for the excretion of uric acid is the primary pathological cause of gout. Levison [13] states that gout is not accompanied by leucocytosis, and therefore the nuclein of leucocytes is not available for the production of uric acid. He considers that gout cannot be developed unless a primary renal lesion is present, and that this is almost invariably of the nature of an interstitial change. Vogel [14] estimated, in three cases of chronic gout, the intake of nitrogen by analysis of the food and the output of nitrogen in the urine and the fæces. He found that there was a nitrogen retention greatly in excess of what could be attributed to a retention of uric acid. Vogel states that his patients behaved in this respect like sufferers from renal disease, although the clinical signs of granular kidney mischief were wanting in all the cases. It must be borne in mind that the absence of the clinical signs of kidney disease does not necessarily imply integrity of those organs.

Association of renal disease with the presence of uric acid in the blood, and with uratic deposits in the joints.—As previously mentioned, von Jaksch found considerable quantities of uric acid in the blood in all the cases of diseases of the kidneys that he examined, and his results were confirmed by Klemperer. It is well known that uratic incrustation of articular cartilages is not uncommonly found at the post-mortem examinations of subjects who have never been known to suffer from ostensible gout during life. Dr. Ord and Dr. Greenfield [15] examined a number of bodies in the post-mortem room for the existence of uratic deposits in the joints and the presence of kidney disease. Among ninety-six cases presenting lesions of the kidneys uratic deposits were found in the joints of eighteen. Dr. Norman Moore, [16] who bases his observations on the results of a large number of post-mortem examinations, states that chronic interstitial nephritis is found in a large proportion of those bodies in which sodium urate is to be seen in the joints. He found that chronic interstitial nephritis is not invariably accompanied by the presence of sodium urate in the articular cartilages, though it is usually accompanied by some traces of degeneration in some of the articular cartilages. He examined the following number of cases, in all of which, as far as could be ascertained, the patients had never suffered from ostensible gout.

Kidney disease.	No. of cases.	Uratic deposit in joint or joints.
Chronic interstitial nephritis...	53	25
Chronic parenchymatous nephritis	11	2

Levison [17] is a strong supporter of the view that there is always some degree of antecedent renal disease connected with gout. In reply to criticisms of this view he points out that the post-mortem examinations of gouty patients have generally shown renal lesions, and that the few exceptional cases are open to criticism. He states that all the post-mortem examinations of patients dying from granular kidney disease at the Communal Hospital, Copenhagen, during a period of fourteen months showed uratic deposits in one or other of the joints, although most of the patients were not known to have had any definite gouty attack. I thought that it would be a matter of interest to ascertain the proportion of cases of uratic deposition in the joints occurring in subjects in whom granular disease of the kidneys was found at the post-mortem examination, and in connection with whom the previous history as to the occurrence or not of gout was known. For this purpose I have obtained the help of some of the pathologists at the London hospitals, who have kindly examined the joints in such cases whenever they were able to do so. I have collected altogether the results of seventy-seven such examinations, for which I am indebted to the kindness of Dr. Cyril Ogle, Dr. F. J. Smith, Dr. Hebb, and Mr. Jackson Clarke. These seventy-seven cases were all cases of granular kidney disease, and in forty-one cases uratic deposits were found in one or more of the joints. The distribution of uratic deposits among the gouty and non-gouty cases is shown in the following table.

TABLE II.—*Showing the Results of the Examinations of the Joints of Seventy-seven Cases of Granular Kidney Disease.*

——	No. of cases.	Uratic deposit in joint or joints.
Known to have had gout... ...	10	10
Never known to have had gout	67	31
Totals	77	41

In the ten patients known to have had gout uratic deposits were found in one or more of the joints of all, and the kidney conditon was in every case described as "markedly granular" or "fairly granular." Amongst the sixty-seven cases of granular kidney disease in patients not known to have suffered from previous gouty attacks uratic deposits were found in one or more of the joints of thirty-one—that is, in 46 per cent. of the cases, which closely agrees with the 47 per cent. found under similar conditions by Dr. Norman Moore. In these sixty-seven cases are included all cases which showed the existence of any granular kidney disease, but several of the cases in which no uratic deposits were found were described as only "slightly granular" or "faintly granular." If from the sixty-seven cases a selection is made of those described as "markedly granular," or as "typical granular" kidneys, then the proportion of cases in which uratic deposits were found in the joints appears as follows.

——	No. of cases.	Uratic deposit in joint or joints.
Marked granular kidney disease	26	20

Thus it is seen that among the cases of marked granular disease of the kidneys occurring in persons who were never known to have suffered from ostensible gout during life uratic deposits were found in the joints of 77 per cent. of

Hosted by Google

the cases. These results, taken in conjunction with those of Dr. Norman Moore and of Levison, show that kidney disease exercises a powerful influence in causing an accumulation of uric acid in the blood and consequently in producing uratic deposits in the joints.

It has been urged that if kidney disease, with the consequent diminished excretion of uric acid, be the primary factor in the causation of gout, signs of kidney mischief would always manifest themselves prior to an attack of gout, and that very few such cases have ever been recorded. But, in the first place, it must be remembered that such signs are not usually looked for, and, in the second place, they need not necessarily reveal themselves clinically. It is well known that contracted granular kidney is not always evidenced either by the occurrence of albuminuria or of dropsy. The contention that if organic renal failure existed the urea excretion would probably be equally affected together with that of uric acid does not hold good, if the view is adopted that uric acid is produced in the kidneys while urea is only eliminated by them. It is well known that in gouty subjects the kidneys have been found at the post-mortem examinations in a diseased condition when there have been no external manifestations during life of the existence of such renal mischief. That uratic deposits are frequently found in the kidneys of gouty subjects is a matter of common experience, but in the absence of such deposits the kidney may still be affected. Sir Dyce Duckworth believes that changes occur in the kidneys of gouty subjects quite independently of uratic deposits in these organs. It has been urged that the renal theory is difficult to harmonise with the hereditary character of gout. It is quite possible, however, that there may be in gouty subjects a hereditary tendency to the renal affection, since both Dr. Dickinson and Eichorst have shown that there is an hereditary tendency to granular kidney.

Kidney disease and gout alike caused by certain toxic agents.—Certain toxic agents which predispose to, or which excite, kidney disease are also known to produce gout. Lead gives rise to both chronic kidney disease and gout. In chronic lead poisoning proliferation of the epithelium of the urinary tubules first occurs, followed by granular atrophy and excessive formation of interstitial tissue. In numerous cases of chronic lead poisoning gout has developed. Very similar changes occur in the gouty kidney, and it seems reasonable to assume that the changes in that organ in both chronic lead poisoning and in gout so affect the excreting apparatus of the kidneys as to seriously diminish their power of eliminating uric acid. That lead poisoning gives rise to the accumulation of uric acid in the blood has been shown by Sir Alfred Garrod. Gout subsequently developed in two cases of plumbism in which the blood was found by him to be rich in uric acid. He also determined the excretion of uric acid in the urine of two patients to whom acetate of lead was medicinally administered. In both patients a well-marked diminution of uric acid in the urine occurred. It was also noticed that after the lead had been given for a day or two the excretion of the uric acid in the urine was suddenly diminished to a very small amount—a condition which usually lasted for a day or two. This points to the fact that lead exercises a marked inhibitory effect on the cells of the kidneys concerned in the excretion of uric acid. The action of the lead is not due to inhibition of the formation of uric acid, since in cases of plumbism the blood becomes charged with uric acid. Alcohol is another body which in excessive quantities gives rise to kidney mischief and which may also give rise to gout.

I think there is abundant evidence to show the connexion between kidney mischief and gout for the following reasons: (1) uric acid has always been found in the blood in cases of renal disease; (2) uratic deposits are fairly frequently found in the joints of persons who have suffered from renal disease, but who have never been known to have had ostensible gout; (3) kidney mischief is frequently met with at the post-mortem examinations of gouty subjects; and (4) certain toxic agents predispose to both kidney disease and gout.

Probable anatomical seat of the kidney affection causing gout.—The anatomical seat of the presumed kidney affection giving rise to the development of gout is probably in the epithelium of the convoluted tubes, as that has been shown by Levison[18] to be the primary seat of disease in granular kidney, and by Oliver[19] to be the seat of the kidney affection associated with lead poisoning. The increase of interstitial tissue is probably a secondary change. My own belief is that a functional affection of the kidneys always precedes any gouty manifestations, and that this functional affection may subside if the exciting cause of it be removed, or it may pass on to a structural lesion. It is the liability to this functional affection of the kidneys which, in my opinion, constitutes the hereditary factor of gout. Such functional affection may, however, be started by various agents and causes, among which are excessive indulgence in nitrogenous foods, wines, and beers, the toxic effect of lead, and the influence of nervous impulses, such as mental shocks, severe accidents, &c. If this view be correct, it is obvious that the kidney condition must always be considered in the treatment of gout, and that, given diseased organs incapable of eliminating the normal amount of uric acid, either some other channel for its elimination must be secured or its formation must be limited to the diminished output, so that absorption of it into the general circulation may be avoided. The retention of uric acid in certain cells of the kidney and its subsequent absorption into the blood is analogous, as Sir Alfred Garrod has pointed out, to an attack of jaundice. When no obstruction exists to the exit of bile from the biliary passages no appreciable amount of its colouring matter is found in the blood, but when its free elimination is checked then absorption of it into the blood speedily takes place.

ORIGIN OF URIC ACID.

I now propose to discuss the various views as to the origin of uric acid, and to consider what its antecedents are and by what chemical processes or by what conjugations it results. A commonly received notion as to the origin of uric acid is that it results from a less perfect oxidation of the nitrogenous constituents of the tissues than occurs when urea is formed. According to this view urea is the ultimate product of the metabolism of nitrogenised tissues in mammals, the formation of uric acid being an intermediate stage of the metabolism. In birds and serpents it has been supposed that the nitrogen is eliminated in the form of ammonium urate without having undergone the further change into urea. This notion is mainly based on the observation of these two facts: (1) that uric acid by means of oxidising agents can be split up into urea and other substances; and (2) that in certain reptiles whose respiration is languid and whose temperature is low the kidneys excrete uric acid to the entire exclusion of urea. The inference that the production of the uric acid in such reptiles is the result of imperfect oxidation is, however, disproved by the well-known fact that birds, whose respiration is rapid and whose temperature is higher than that of mammals, also, like reptiles, excrete uric acid to the exclusion of urea. So that, although uric acid is a less highly oxidised product than urea, it is very doubtful whether it can be considered as an antecedent in the formation of urea.

Another commonly received notion is that gout is accompanied by an excessive formation of uric acid, which is usually attributed to the ingestion of a too highly nitrogenised diet, and especially to an animal one. Virchow,[20] however, considers that a too highly nitrogenised diet is not necessarily the cause of gout, because he has often observed gout in poorly fed convicts. Gout is certainly not incompatible with a vegetable diet, as amongst certain birds kept in captivity and living exclusively on grain uratic deposits have been observed around the joints. On the other hand, animal food does not necessarily produce uric acid in a healthy system, as is shown by its absence from the urine of some of the carnivora. It is true that the ingestion of very large quantities of proteid matter is followed by an increased production of uric acid, and *vice versâ*, but apparently it makes little, if any, difference whether the proteid matter is of animal or of vegetable origin. The only reason that a vegetable diet is less productive of uric acid than an animal diet is in the fact that the former is poorer in proteid material, and therefore to consume in the vegetable diet as much proteid matter as is ordinarily consumed in an animal diet would require the ingestion of a very large bulk of vegetable food. Therefore, the assumption is not altogether correct that the total daily excretion of uric acid is greater on an animal than on a vegetable diet. With the same intake of nitrogen in the two diets there is practically no difference in the uric acid output. This is shown by the experiments of Bleibtreu,[21] who examined his urine after

[18] Loc. cit.

Hosted by Google

three days' flesh diet and after three days' vegetable diet. Although after the flesh diet there was a considerable rise in the amount of urea excreted, there was very little difference in the uric acid excretion. After the three days' flesh diet the uric acid excreted in twenty-four hours was 0·859 grm., while after the three days' vegetable diet it was 0·791 grm. Similar results were obtained by Hirschfeld,[22] who found that on a diet very poor in nitrogen he excreted daily 0·417 grm. of uric acid, on one rich in albumin 0·386 grm., and in a highly albuminous diet 0·492 grm. That the production of uric acid is not dependent, at all events, to any great extent, on diet is also shown by the fact that the same diet which in one class of animals will produce uric acid will in another class produce urea. Thus in the urine of the carnivorous lion and tiger there is a quantity of urea and but very little uric acid; on the other hand, the carnivorous python and boa excrete uric acid and no urea. Graminivorous birds excrete uric acid and no urea, whilst herbivorous mammals excrete quantities of urea and but little or no uric acid.

Sir William Roberts,[23] comparing the functions of the kidneys of birds and serpents with those of mammals, considers that an immense functional evolution has taken place in the mammalian kidney—that the evolution of mammalian urine has probably turned mainly on the point that the mammalian plan required that the renal excretion should be voided not in the solid or semi-solid form, but as a watery solution. This modification would require the discarding of the sparingly soluble uric acid as a medium for the elimination of nitrogen and the substitution of a nitrogenous substance readily soluble in water, such as urea. He considers it possible that the reason why this substitution has not been completely effected is that in that particular the mammalian type has not yet reached its ideal perfection and that the residuum of uric acid in mammalian urine may be something in the nature of a vestigial feature.

View that uric acid is formed from urea in the kidneys.—In mammalia, including man, and in birds uric acid is absent from the blood in health, while urea is always present in the blood. The blood of the renal artery is much richer in urea than the blood of the renal vein—according to Picard in the proportion of about two to one, according to Sir Alfred Garrod in the proportion of about three to one. From his most recent observations Sir Alfred Garrod[24] concludes that in birds and other uric acid excreting animals the metabolism of the nitrogenised tissues is exactly the same as in mammals. He believes that urea is the ultimate product of this metabolism, and that the uric acid is a subsequent product of the union of urea with some other principle or principles, glycocine probably being one of them. He regards the kidney as the organ whose function it is to manufacture uric acid from the nitrogenised matters brought in the blood, and considers it possible that the kidney contains different cells—some for the formation of urea and some for the formation of uric acid—and that the ratio between the two may vary in different classes of animals. One very strong argument against the formation of uric acid in the liver, spleen, connective tissues, &c., is that it is never present in the blood of mammals (including man) and of birds in health. If it were formed in such organs or tissues it must be conveyed in the blood to the kidneys. Since, according to Sir Alfred Garrod's and my own investigations, urea, and not uric acid, is found in the blood of birds, and since uric acid, and not urea, is found in the urinary excrement of birds, it seems highly probable that urea is at least one of the sources of formation of uric acid and that the change is effected in the kidneys. Dr. P. W. Latham's[25] explanation of the formation of uric acid in the animal economy is that the amido bodies, glycocine, taurine, leucine, and tyrosine, are normally converted in the liver into urea; but if from any cause the metabolism of glycocine be interrupted there would then be present in the liver glycocine and urea, which would produce hydantoic acid and then hydantoin, and the latter, which is freely soluble, would then pass on in the circulation to unite in the kidneys with urea or with biuret to form an ammonium salt of uric acid. Therefore according to this view the imperfect metabolism of glycocine is the primary and essential defect in connexion with the abnormal formation of uric acid in the human system.

[25] Croonian Lectures, THE LANCET, April 3rd, 10th, 17th, and 24th, and May 1st, 1886.

According to Dr. Latham, the synthesis of uric acid from urea and glycocine takes place in the following steps:—

I. The urea and glycocine produce hydantoic acid:

$$\underset{\text{Urea.}}{CH_4N_2O} + \underset{\text{Glycocine.}}{C_2H_2(NH_2)O.OH} = \underset{\text{Hydantoic acid.}}{C_3H_6N_2O_3} + NH_3.$$

II. The hydantoic acid becomes dehydrated and forms hydantoin:

$$\underset{\text{Hydantoic acid.}}{C_3H_6N_2O_3} = \underset{\text{Hydantoin.}}{C_3H_4N_2O_2} + H_2O.$$

III. From more of the urea biuret is produced:

$$2\,\underset{\text{Urea.}}{CH_4N_2O} = \underset{\text{Biuret.}}{C_2H_5N_3O_2} + NH_3.$$

IV. By combination of hydantoin and biuret uric acid is produced:

$$\underset{\text{Hydantoin.}}{C_3H_4N_2O_2} + \underset{\text{Biuret.}}{C_2H_5N_3O_2} = \underset{\text{Uric acid.}}{C_5H_4N_4O_3} + NH_3 + H_2O.$$

The production of uric acid from urea and glycociine may be shown in a single equation as follows:—

$$3\,\underset{\text{Urea.}}{CH_4N_2O} + \underset{\text{Glycocine.}}{C_2H_2(NH_2)O.OH} = \underset{\text{Uric acid.}}{C_5H_4N_4O_3} + 3NH_3 + 2H_2O.$$

There are several reasons for believing that uric acid may be formed from urea and glycocine in the living organism. Horbaczewski produced uric acid by the interaction of urea and glycocine, and this result was confirmed by Dr. Latham. Glycocine is certainly formed in the human body, and probably is one of the antecedents of urea, for in man glycocholic acid, a compound of glycocine and cholic acid, passes in the bile into the intestine, and having served its purpose, and its constituents having been set free, the glycocine together with the other amido bodies, taurine, leucine, and tyrosine, pass in the portal blood to the liver, and probably in the hepatic cells are converted into urea. That glycocine is concerned in the production of uric acid is somewhat probable from the fact that in the carnivora, whose urine contains little or no uric acid, the bile contains no glycocholic but only taurocholic acid, and therefore yields no glycocine. The experiments of Hahn, Massen, Nencki, and Pawlow also support the view that glycocine is concerned in the formation of uric acid. They shut the livers of dogs almost completely off from the general circulation by diverting the portal circulation into the inferior vena cava, and found that, although the dogs passed less urea (the nitrogen being mainly eliminated as ammonium carbonate), the uric acid voided was considerably increased. Dr. Latham[26] believes that if an excessive amount of nitrogenous material is introduced into the portal circulation the portion which is least readily acted upon is the glycocine, the presence of which promoted the formation of uric acid. He considers that the primary defect in gout consists in the imperfect metabolism of glycocine.

It is quite possible that there is another means by which uric acid may be formed from urea. Gérard[27] has succeeded in converting uric acid into urea by the agency of micro-organisms derived from the air, and Magnier de la Source has effected a similar conversion by purely chemical agencies. The reaction is one of hydration, the uric acid uniting with the elements of water and yielding urea and tartronic acid, as shown in the following equation:

$$\underset{\text{Uric acid.}}{C_5H_4N_4O_3} + 4\,H_2O = 2\,\underset{\text{Urea.}}{CH_4N_2O} + \underset{\text{Tartronic acid.}}{C_3H_4O_5}.$$

One may therefore conjecture that the formation of uric acid from urea by the reversed action is at least possible. Though tartronic acid is not known to exist in the human body, it can be derived from lactic, malic, succinic, or tartaric acids. We may therefore conclude that the conversion of urea into uric acid by the agency of certain of the kidney cells is at least possible either by the conjugation of urea and glycocine or by the interaction of urea and tartronic acid, the last mentioned body being possibly derived from lactic acid.

Uric acid formation and liver disease.—If uric acid be formed in the kidneys from urea and glycocine brought from the liver, it can be readily understood that alterations in the metabolism of the liver must necessarily affect the formation and excretion of uric acid. This would explain why liver trouble of some kind or another is so commonly associated with gouty dyspepsia and also renders intelligible the fact that several observers have been unable to dissociate the

Hosted by Google

connexion between liver troubles and gout, and have therefore attributed the formation of uric acid to the liver. For instance, Dr. Murchison considered that gout is an hereditary disease by virtue of the transmission by parents to their offspring of a defective power of the liver, in virtue of which its functions are deranged with unusual facility; as a result of this derangement of the liver the metabolism of the albumin is to a great extent arrested at the stage of uric acid formation, instead of going on to the final stage of urea formation. Dr. George Harley considered that a strong relationship existed between gout and hepatic derangements. Sir Dyce Duckworth[28] is of opinion that "the liver is the organ in which in health uric acid is chiefly formed, and it is probably to derangement of function in this gland that we must look for over-production of this substance."

View that uric acid is formed from nuclein.—Horbaczewski[29] has shown that uric acid, as well as xanthin and hypoxanthin, can be prepared from spleen pulp. By digesting fresh spleen pulp with hot water till changes set up by bacterial agency are started he found that the fluid when freed from albuminous bodies contained xanthin and hypoxanthin, but no uric acid. By treating this fluid with arterial blood and keeping the mixture at from 40° to 50° C. uric acid forms in it after several hours. A similar result is produced by using as the oxidising agent either a dilute solution of hydrogen peroxide or an abundant supply of atmospheric air. Horbaczewski found that the nitrogen contained in the uric acid so formed was about equal in amount to the nitrogen contained in the xanthin and hypoxanthin (xanthin bases). So that there exists in the spleen nitrogenous substances which can be transformed, at all events in part, into xanthin bases or into uric acid. The xanthin bases when once formed cannot be further oxidised into uric acid. Horbaczewski brings forward proof that the substance which yields xanthin bases and uric acid is the nuclein of the spleen cells. It was found that when pure nuclein prepared from spleen pulp was dissolved in very weak alkali and digested with blood at 40° C. uric acid was formed. Sadowenj and Formanck have shown that uric acid can be prepared in a similar manner from almost all the tissues and organs of the body, and conclude that the nuclein contained in the cells is the mother substance.

It having thus been shown that uric acid can be prepared from nuclein outside the system, the next problem to solve was whether a similar decomposition also occurred in living human beings. Horbaczewski found that the excretion of uric acid can be increased either by the administration of nuclein with food or by the subcutaneous injection of a solution of it. Umber[30] found that the administration of a large amount (500 grammes per diem) of food like thymus, which contains a considerable quantity of nuclein, increases the excretion of uric acid as compared with its excretion when a similar amount of flesh is given. The same amount of liver given to one person caused an effect similar to that caused by thymus, but in others its action was less marked. Kidney and brain administered as food yielded nearly the same amount of uric acid as flesh.

From his experiments Horbaczewski concludes that uric acid is formed in health by the disintegration of nuclein, and that sudden variations in uric acid production may be due to the breaking up of leucocytes and conversion of their nuclein into uric acid or xanthin bases within the system. It has been shown by many observers that a temporary or permanent leucocytosis is always accompanied by an increased excretion of uric acid. A relationship between the number of leucocytes in the blood and the excretion of uric acid is observable in human beings during fasting and after taking food. During fasting the number of leucocytes diminishes and the amount of uric acid excreted falls; after taking food the number of leucocytes increases and the amount of uric acid excreted rises. The increase in the number of leucocytes in the blood after a meal appears to be due, at all events in part, according to Hofmeister,[31] to the rapid increase of lymph cells in the adenoid tissue of the stomach and intestines during digestion, whence they are discharged into the lymph stream and finally into the blood. Gamprecht,[32] who uses the term "alloxur bodies" in Kossel and Krüger's sense, as meaning those bodies which have an alloxan and urea nucleus, and therefore as including, besides uric acid, xanthin, guanin, hypoxanthin, adenin, and their derivatives, found that in the exceptional cases of leucocythæmia in which the uric acid excretion is normal or diminished the alloxur bases are increased and that their amount varies directly with the amount of leucocytosis. He gives one case of his own in which this is shown very clearly, and points out that it forms an additional support to Horbaczewski's view that uric acid comes from degeneration of leucocytes and is formed from their nuclein.

From a consideration of all the work that has been done in connexion with leucocytosis and the excretion of uric acid it is clear that there is no constant ratio between the number of leucocytes and the amount of uric acid excreted, for there may be leucocytosis without increase of uric acid, as there may be an increase of uric acid without leucocytosis. I think that in cases of leucocythæmia, severe anæmia, &c., where uric acid is present in the blood, it is probably derived from the nuclein of leucocytes or other cells. It is, however, in my opinion, wrong to draw the further inference that the source of the uric acid excreted in health is the nuclein derived from leucocytes throughout the body. If such were the case, uric acid would be found in the blood in health, but, as previously shown, it is not. Moreover, in birds there is no special leucocytosis to account for the large formation and excretion of uric acid that occurs.

View that part of the uric acid is introduced ready formed in food.—Dr. Haig, who, in my opinion, wrongly ascribes to uric acid an almost universal *rôle* in the causation of disease, claims that the uric acid excreted in the urine comes from two sources—(1) the uric acid which is formed in the body out of nitrogenous food; and (2) the uric acid introduced into the body ready formed in certain articles of diet, such as meat, meat extracts, soup, tea, coffee, &c. He considers that flesh diet increases both the introduction and the formation of uric acid, a view which is opposed to the previously quoted experimental results obtained by Bleibtreu and by Hirschfield. Dr. Haig[33] gives the quantities of uric acid which a man may introduce into his system with an ordinary dinner as follows:—

					Grain.
8 ounces	soup,	containing 0·02	per cent.	uric acid =	0·70
2 ,,	fish,	,, 0·03	,,	,, =	0·26
3 ,,	meat,	,, 0·04	,,	,, =	0·52
½ drachm	meat extract,	,, 0·80	,,	,, =	0·24
					1·72

As far as I can ascertain from Dr. Haig's writings he has never identified by the murexide test this uric acid reported to be present in these various articles of diet. Apparently, these estimations depend solely on the application of Haycraft's process to the articles of diet, and the subsequent calculation of the silver precipitate so obtained in terms of uric acid. Dr. Haig[34] writes: "I have all along felt that in applying Haycraft's process to extracts of tissues I was walking on dangerous ground as regards theoretical chemistry, and I have therefore been careful to point out that, while I gave figures of the amount of uric acid found in various animal foods by this process, the only satisfactory test of the amounts of these compounds contained is the physiological one of eating a known quantity of the substance in question, and watching the effects on excretion in the urine." That Dr. Haig's peculiar view as to the direct introduction of uric acid in articles of diet is an erroneous one is shown by the absence of uric acid from the blood of man and animals in health. Dr. Haig has also advanced the theory that normally there is a constant ratio of 1 to 35 between the uric acid and urea formation, and that if the uric acid excretion falls below this ratio it is due to the retention and storage of uric acid in the liver, spleen, kidneys, joints, and fibrous tissues, whereas an increase in the proportion of uric acid to urea is due to the washing out from its storage places of the deposited uric acid. According to this view the amount of uric acid produced in each individual is a constant factor, the variations in the amounts eliminated being due, on the one hand, to excessive storage, and on the other to the discharge of the stored up supply. This theory of the existence of a normal ratio of uric acid to urea, and of every departure from it being due to a pathological cause, is disproved by the following experiments. Bleibtreu and Schultze,[35] experimenting on themselves,

showed that the ratio between uric acid and urea can be considerably altered by means of the diet without the general health being influenced. 2. Dr. Herringham and Mr. Groves,[36] as the result of a series of experiments that they made, entirely fail to corroborate Dr. Haig's observations and think that either what was true for his system was not true for theirs, or that Dr. Haig's results were, to quote their own words, "inaccurate and deceptive owing to his having employed a very uncertain and inaccurate method for the estimation of uric acid." 3. The following results of the determinations that I have made of the total daily eliminations of uric acid and urea in the urine of a healthy adult man, and which consist of observations extending over a period of fifty days, show that the ratio of uric acid to urea varied from 1:28 to 1:55 (the average being 1:42), although throughout the entire period the individual remained in good health.

Daily average in grains	9·8	415·0	1:42
Average in twenty-four hours for each pound of body-weight (in grains)	0·07	3·19	—

It is evident from the above results that no constant ratio exists in a given individual between the excretion of uric acid and urea. Variations in the daily elimination of uric acid in healthy individuals are not due to the sweeping out of uric acid from the different organs and tissues into the blood, for uric acid is never found in the blood of healthy persons. Differences from day to day in the uric acid excretion probably depend upon the amount of glycocine leaving the liver and passing on to the kidneys; this factor would be affected by variations in the metabolism of the liver, which may be induced by changes in the quality or quantity of the diet, by the amount of exercise, and by various nervous influences. Dr. Latham[37] has suggested a possible reason why those persons who have a tendency to gout and who take little exercise tend to develop the disease. It is that insufficient muscular exercise tends to the formation of glycocine. This is seen in the case of horses, which when put to hard work eliminate benzoic acid in the urine, but if kept in the stable for some time benzoic acid appears in the urine in combination with glycocine as hippuric acid, which is benzoyl-glycocine.

Different modes of formation of uric acid in health and in blood disorders.—From a consideration of the various views as to the origin of uric acid I think it is evident that there are two distinct and different ways in which it may originate. 1. In health I believe that it is only formed in the kidneys, probably from urea and glycocine, and that it is at once eliminated in the urine. If from any functional or organic affection of the uric acid eliminating cells of the kidneys its proper excretion is inhibited, then it is absorbed into the general circulation and constitutes the store from which the uratic deposits of gout are formed. 2. In diseases which are accompanied by leucocytosis I believe that uric acid may be formed from the nuclein of leucocytes in the spleen and possibly throughout the system generally, but that such uric acid is readily eliminated by the kidneys which remain sound as regards their uric acid secreting structures; consequently gouty deposits never occur in connexion with such diseases. The two different modes of formation of uric acid might be distinguished as the urea formation and the nuclein-formation of uric acid.

CAUSES OF URATIC DEPOSITION IN GOUT.

As I take the view that the uratic deposits of gout are derived from uric acid absorbed into the blood from the kidneys, I propose to consider now the various causes for its crystallisation from the blood and the reasons why it selects certain tissues as seats for its deposition. It is necessary to briefly consider (*a*) the form in which uric acid is absorbed into and circulates in the blood, and (*b*) the form in which it is deposited from the blood or fluids of the body.

Form in which uric acid exists in the circulation.—Sir William Roberts[38] has shown that the amorphous urate deposit of human urine is of the same composition as the solid or semi-solid urinary excrement of birds and serpents, the only difference being one of physical form. The deposit from human urine is amorphous, whilst the urinary excrement of birds and serpents consists of minute crystalline spheres. Sir William Roberts shows that this difference in physical form is a mere accident of molecular aggregation, since under certain conditions the amorphous urate deposit can be transformed into crystalline spheres, whilst the crystalline urinary substance of birds and serpents can be converted into amorphous deposit. Dr. Bence Jones[39] was the first to show that the amorphous urate deposit yielded to water a soluble moiety

[37] On the Formation of Uric Acid in Animals, 1884, p. 42.
[38] Loc. cit.
[39] Journal of the Clinical Society, 1862, vol. xv., p. 201.

Hosted by Google

consisting of true biurate and left a sediment consisting of pure uric acid, and from the results of his analyses he inferred that the amorphous urate deposit consisted of, or at least often contained, a molecule of biurate in loose combination with a further molecule of uric acid. Sir William Roberts took up and continued the investigation dropped by Dr. Bence Jones thirty years before, and has conclusively shown that a third order of uric acid salts—the quadriurates—exists and that the amorphous urate deposit of human urine and the urinary excretion of birds and serpents belong to this order, and consist of a true and definite compound of biurate and uric acid in the proportion of one molecule of each. Sir William Roberts concludes that the quadriurates are the physiological combinations of uric acid. They exist normally in the urine and constitute the only form in which uric acid exists in normal urine. All the morbid phenomena due to uric acid probably arise from secondary changes in the quadriurates. The amorphous urate or quadriurate deposit of urine is generally referred to as consisting of a mixture of the potassium, sodium, ammonium, and calcium urates. As far as I can ascertain, however, no quantitative determination of the bases in the deposit has yet been made. The nearest approach to it is an analysis made by Sir William Roberts[40] of a sample of amorphous urate deposit prepared by an artificial process with potassium carbonate, and which would therefore most probably contain more potassium than the natural deposit. I therefore considered it advisable to determine the actual bases present in the amorphous urate deposit and their relative proportions. The deposit was obtained from several gallons of acid urine passed by patients suffering from febrile diseases, and was collected in a filter and allowed to drain. It was decomposed by boiling with distilled water and excess of hydrochloric acid, allowed to cool, filtered from the deposited uric acid, and the filtrate, which then contained the bases in the form of chlorides, was evaporated to dryness. The residue was taken up with distilled water, filtered from the minute amount of uric acid left in solution after the precipitation of the bulk of the acid, and evaporated to dryness. Part of the residue was submitted to qualitative analysis and found to consist of ammonium, sodium, and potassium, with very small traces of calcium and magnesium. The amounts of ammonium, sodium, and potassium were then estimated in the usual manner in the other portion, when their relative quantities were found to be as follows:—

	Parts per 100.
Ammonium	46
Sodium	40
Potassium	14

These amounts calculated as the respective quadriurates would approximately give the following composition for the amorphous uratic deposit that naturally forms in acid febrile urines: 7 molecules $NH_4HC_5H_2N_4O_3$, $H_2C_5H_2N_4O_3$ (ammonium quadriurate); 5 molecules $NaHC_5H_2N_4O_3$, $H_2C_5H_2N_4O_3$ (sodium quadriurate); 1 molecule $KHC_5H_2N_4O_3$, $H_2C_5H_2N_4O_3$ (potassium quadriurate). The uric acid which is formed in the kidneys is probably at once converted into the mixture of these three quadriurates, which in the normal state are then excreted dissolved in the urine. If, however, any absorption of them takes place into the blood, as probably occurs in the gouty state, the ammonium and potassium quadriurates would be converted by the sodium carbonate of the blood into sodium quadriurate, which would constitute the sole compound of uric acid circulating in the blood. It is from this body that the sodium biurate, of which the gouty deposits consist, is formed.

Formation of the sodium biurate from the quadriurate.—Sir William Roberts investigated the behaviour of free uric acid with blood serum and kindred media with the object of endeavouring to throw light on the mode in which sodium biurate originates in the body and on the conditions which control the precipitation of sodium biurate in the gouty system. He worked with solutions of uric acid in blood serum and in a standard solvent which was prepared as follows.

Composition of Sir William Roberts's standard solvent.—Sodium chloride, 0·5 gramme; sodium bicarbonate, 0·2 gramme; and distilled water, 100 c.c. This solution represents the blood serum, in so far as its saline ingredients are concerned. Sir William Roberts found that it reacted with uric acid and the urates in the same manner as blood serum itself, and in the same manner as a solution comprising all the salts of the serum in their proper proportions. He found that blood serum and the standard at the temperature of the human body both dissolved uric acid to the extent of about one part in 500, thus exhibiting about twenty times the solvent power that the same media exercise on sodium biurate. The chemical and solvent power is dependent on the sodium carbonate contained in them, and is due to that body converting the uric acid into sodium quadriurate. This sodium quadriurate which remains in solution is gradually converted by the excess of sodium carbonate into sodium biurate, and this on account of its lesser solubility is eventually precipitated in the crystalline form. Sir William Roberts infers from these results that in the normal state uric acid is primarily taken up in the system as quadriurate, and that as such it circulates in the blood. The detained quadriurate, circulating in a medium rich in sodium carbonate, is gradually transformed by the latter into sodium biurate, which is less soluble and is probably less easily excreted by the kidneys than the quadriurate. This biurate is probably not precipitated at once, since it would most probably pass at first into the hydrated or gelatinous condition, which is a much more soluble modification of sodium biurate than the crystalline form; but with due lapse of time and increasing accumulation it passes into the anhydrous or crystalline condition, and as this form is almost insoluble precipitation of it occurs or is likely to occur. The reason that in leucocythæmia and other blood diseases no uratic deposits occur is that the uric acid produced in the various organs or tissues is discharged into the blood as a quadriurate, and as this requires some hours for its maturation before it is possible for it to deposit sodium biurate there is abundant time for the kidneys to eliminate it, provided these organs are sound. In connexion with gout, if the view be correct that defective elimination of uric acid by the kidneys always occurs, the conditions are quite different. In gout uric acid is absorbed from the kidneys into the general circulation owing to the partial failure of the uric acid excreting function of the kidneys. The uric acid is absorbed as the sodium quadriurate, which, dissolved in the blood, gradually passes through the maturation process and forms sodium biurate. When the amount of the biurate in the blood is more than that fluid can retain in solution then deposits of it occur in those tissues which, either on account of having received previous slight injuries or because of their poor vascular supply, specially favour its deposition.

SEATS OF URATIC DEPOSITS IN GOUT.

Uratic deposits are found almost exclusively in structures belonging to the connective tissue class—in cartilages, ligaments, tendons, and in the cutaneous and subcutaneous connective tissue. They are conspicuously absent from the muscular tissue, and from the substance of the liver, spleen, brain, and lungs. Uratic deposits have been very occasionally found in the following places: In the mitral and aortic cardiac valves, in atheromatous patches in the aorta, in the walls of veins, in the crico-arytenoid ligaments, in the vocal cords, in the walls of bronchial tubes, in the mucous follicles of the pharynx, upon the meninges of the brain and spinal cord, upon the spinal nerve sheaths, in the sclerotic coat of the eye, and the fibrous envelope of the retina. It is always in the fibrous tissue which participates in the formation of the nervous envelopes that the deposit is found. Uratic crystals have also on two occasions been detected in the sputa of gouty patients. Sir William Roberts considers that the visceral neuroses and the thrombosis and embolism met with in gout are not the result of the dissolved uric acid in the blood, but are due to precipitation of minute crystals of sodium biurate either in the substance of the organs or in the blood itself.

Anatomical seat of the deposit in cartilages.—The uratic deposit first occurs in the central portion of articular cartilage—a point farthest from the network of nutrient capillaries and a point whose nutrition is more easily retarded. It is also probably the point of greatest pressure; hence a long walk, a dance, or similar violent exercise may precipitate an attack of gout. Uratic deposits occur in cartilages, ligaments, synovial membranes, and their fringe-like processes. In synovial membranes the deposit is not on the surface, but in the subserous tissue. Ebstein states, as the result of the examinatiom of a typical gouty knee-joint,

[40] Loc. cit., p. 20.

Hosted by Google

that directly under the surface of the cartilage a very shallow tissue layer exists in which crystals are wanting, and in the layer immediately beneath this the crystals are most plentiful. He agrees with Sir Alfred Garrod that only two-thirds of the thickness of the cartilage is usually infiltrated, although exceptionally—as shown by Cornil and Ranvier—the whole cartilage may be infiltrated. With regard to the exact relation of the uratic deposit to the various elements of articular cartilage the cartilage cells are held to be the centres of primary deposit by Cornil and Ranvier, Charcot, Rindfleisch, Budd, and Garrod. Cornil and Ranvier consider that nutritive disturbances in the cartilage cells precede the deposition of sodium urate. Rindfleisch and Budd, however, consider that the cartilage cells do not take any active part. Some observers, including Sir Dyce Duckworth, consider that the deposition occurs quite indiscriminately, not selecting for its original site any particular element of the cartilage. Others, as Bramson, Rokitansky, and Auguste Foerster, think that urates deposit in the intercellular cartilaginous substance.

THE ADMINISTRATIVE TREATMENT OF UNDEFINED CASES CERTIFIED AS SCARLET FEVER.

BY FREDERICK DITTMAR, M.A., M.D. GLASG.,

AND

JOHN BROWNLEE, M.A., M.B. GLASG.,

LATE AND PRESENT ASSISTANT MEDICAL OFFICERS IN CHARGE OF THE CITY OF GLASGOW FEVER HOSPITAL, KENNEDY-STREET.

IN this communication we intend giving an account of the management of the undefined cases admitted to the City of Glasgow Fever Hospital, Kennedy-street, from November, 1895, to November, 1896. Prior to the former date there was no arrangement for the special observation of cases of this nature. The hospital, which is exclusively employed for the treatment of scarlet fever, consists of fourteen wards built on the pavilion system, and has accommodation for about 320 patients. The pavilion chosen for the purpose of isolation consists of three divisions separated one from another by brick partitions which extend from floor to ceiling, while each division has a separate communication with the outside. Two of them have a capacity of 16,500 cubic feet each, and the third of 8000 cubic feet. The last has also separate latrine accommodation and bathroom.

The patients sent to the pavilion were of three classes: (1) cases in which the appearances on admission did not justify a positive diagnosis of scarlet fever; (2) cases where the symptoms and appearances suggested some other disease—e.g., tonsillitis or non-specific erythema; and (3) cases of undoubted illness where the symptoms were obscure, but suggestive of some other infectious disease—e.g., enteric fever. Cases in which some other infectious disease was frankly present were immediately transferred to the Belvidere Fever Hospital without admission to the wards.

The two larger divisions were used for the first two classes, and the smallest division for the third class of cases. The whole pavilion was under the supervision of a very careful and experienced charge nurse whose powers of observation could be relied on, while each division had its special staff of day and night nurses. During their residence in the ward the patients were carefully observed for signs of scarlet fever, the urine being examined twice daily for albumin and evidence of desquamation carefully looked for. As soon as desquamation became definite or scarlet fever complications showed themselves the patient was transferred to a scarlet fever ward, where he completed the statutory period of eight weeks in hospital. Cases which did not turn out to be scarlet fever were kept in the isolation ward for a period varying with the nature of the case, but as a rule were not dismissed under four weeks, which we considered long enough for any such definite evidence as desquamation or nephritis to develop. None of the cases dismissed from the isolation ward were sent back to hospital with evidences of scarlet fever. The main objection which we have heard raised against the kind of arrangement adopted by us is that now and again patients who ultimately prove to have scarlet fever are mixed with those who do not, and thus may infect the others. Our experience seems to show that this fear is more or less baseless, as no case of scarlet fever occurred in the isolation ward.[1] We tried to minimise the risk of infection by putting the patients at as great a distance from one another as possible and allowing at least 4000 cubic feet of air space to each. We also cautioned the nurses to take special care when attending a patient the subject of any inflammatory secretion by which infection might be carried.

The number of cases observed by us amounted in all to 45, and they fall into the following groups, of the more important of which we give typical examples. Of the 45 cases observed, 11 (24·4 per cent.) ultimately proved to be cases of scarlet fever, 6 (13 3 per cent.) belonged to the class of doubtful scarlet fever, and 28 (62·2 per cent.) were not scarlet fever. The last class was made up as follows: tonsillitis, 11 cases; non-specific eruptions, 4 cases; dermatitis, 2 cases; cellulitis, 2 cases; measles (?), 2 cases; rotheln (?), 1 case; broncho-pneumonia (one complicated with marasmus), 2 cases; gangrenous ulceration of throat, 1 case; general tuberculosis (?), 1 case; and not classed, 2 cases.

CASES 1 AND 2. *Examples of cases ultimately classed as scarlet fever.*—A girl, aged thirteen years, was admitted to hospital on Jan. 31st, 1896, with a history of illness beginning two days previously with sore-throat, sickness, and vomiting. A rash was said to have been seen on the hands. On admission there was no evidence of a scarlet fever rash and the temperature was 100°F. The faucial pillars and soft palate were injected, and there were specks of creamy exudation in the follicles of the tonsils. The glands at the angle of the jaw were slightly enlarged. On Feb. 6th characteristic desquamation was observed, beginning on the neck; slight albuminuria had been observed for a few days prior to this. The patient, who had been sent to the isolation ward on admission, was transferred to a scarlet fever ward, from which she was dismissed on April 4th.

A girl, aged six years, was admitted to hospital on Sept. 5th, 1896, with a history of illness beginning three days before with sore-throat. A faint rash was said to have been observed on the second day on the limbs. On admission there was no evidence of a scarlet fever rash; the temperature was 100·2°F.; the pulse was 100; the tongue was slightly furred; the fauces and tonsils were acutely congested and there was exudation in the follicles of the tonsils; and the cervical glands were slightly enlarged. No definite desquamation was observed in this case. The patient suffered from enlarged cervical glands, rheumatic pains in the joints, and (in the third week) albuminuria. On Oct. 4th she was transferred to a scarlet fever ward, from which she was dismissed well on Nov. 4th.

CASE 3. *Example of cases classed as doubtful scarlet fever.*—A girl, aged five years, was admitted to hospital on July 13th, 1896, with a history of illness beginning five days previously with sore-throat, sickness, and vomiting. No rash had been observed. On admission there was no evidence of scarlet fever rash. The temperature was 101·2°F. and the pulse was 120. Conjunctivitis and coryza were present; the lips were excoriated; there was herpes on the left cheek; the throat was congested generally, and the tongue slightly furred. A trace of albuminuria was observed for a day or two after admission, but not afterwards. Later a few pinholes were observed on the pads of the distal phalanges of the fingers, but there was no distinct desquamation. She was dismissed well on Oct. 21st, having been kept in on account of an accident.

CASE 4. *Example of cases classed as tonsillitis.*—A boy, aged nine years, was admitted to hospital on Nov. 22nd, 1895, with a history of illness beginning two days previously with headache and sore-throat. There was no history of rash. Two other members of the family, suffering from undoubted scarlet fever, were admitted to the hospital a few days before. On admission there was no evidence of a rash; the

[1] It happened during a press of work that one division of the isolation ward was used for a short time for cases of acute scarlet fever which had been sent in suffering from a concurrent attack of measles. The division was fumigated with sulphur and the windows were left open for two months before it was again used for isolation purposes. A case of simple tonsillitis was then placed there alone, with special nurses, and three weeks after admission the patient developed scarlet fever. The only source of infection at the time seemed to be the dust of the ward, and it has little bearing on our general contention.

Hosted by Google

temperature was 99·4° F. The throat was mildly, if at all, injected; the tonsils were chronically enlarged, and the tongue was covered with a thin white fur through which the papillæ appeared prominent. No desquamation or scarlatinal complication supervened, and the patient was transferred to the isolation ward on Dec 7th, from which he was dismissed on Jan. 1st, 1896, nothing having occurred to warrant the diagnosis of scarlet fever.

CASE 5. *Example of cases classed as dermatitis.*—A man, aged twenty-one years, was admitted to hospital on April 8th, 1896, with a history of illness beginning two days before with sickness and headache. A rash was seen on the second day. The patient said that he had had a similar condition before. On admission there was a general erythema of the forearms and of the legs below the knees. The tongue was furred and the throat generally was somewhat congested. The temperature was 100 4° F. A desquamation followed over the parts affected with the erythema. He was dismissed on May 5th.

CASE 6. *Example of cases classed as cellulitis.*—A boy, aged two and a half years, was admitted to hospital on July 15th, 1896. No history accompanied the patient. The child had been dismissed from the Belvidere Fever Hospital after an attack of measles on July 6th. On admission to the City of Glasgow Fever Hospital, Kennedy-street, a dark patchy rash was present on the chest, limbs, and ears; the lips were dry, cracked, and covered with crusts; the dorsum of the tongue was covered with white patches; the left cheek was swollen and glazed; but the mucous membrane of the mouth looked natural. The left forearm and hand were swollen, and the tissues of the upper arm and axilla were swollen and red and pitted on pressure. There was no albuminuria. The temperature was 103° F., the pulse was 160, and the respirations were 60. Free incisions were made in the arm, but the cellulitis spread, and death occurred on July 17th.

CASE 7. *Case of ulcerative inflammation of the throat (non-scarlatinal).*—A boy, aged three years, was admitted to hospital on Feb. 1st, 1896, with a history of illness beginning two days previously with sore-throat. There was no history of rash, and on admission there was no evidence of a rash. The temperature was 101° F. The fauces were injected, and the tonsils were large, the glands in the neck being slightly enlarged. The tongue was furred, but the papillæ were not injected. Coryza and conjunctivitis were present. Nothing suggestive of a scarlet fever or measles rash was observed. The local condition in the throat became worse with rapidly advancing ulceration and necrosis, resulting in death on Feb. 10th. A post-mortem examination was not allowed.

CASE 8. *Case of non-specific eruption.*—A woman, aged twenty-seven years, was admitted to hospital on Dec. 19th, 1895. The patient stated that an eruption had been observed two days before, unaccompanied by malaise or sore-throat. She had been eating some patent sweetmeat for some days before. On admission the temperature was 98·4° F. The throat and tongue were natural. There was a general erythema over the upper extremities; over the forearms, in addition, were numerous, slightly raised erythematous spots, fading on pressure. Over the legs below the knees and on the dorsa of the feet there was a general erythema, fading on pressure. On the extensor aspect of the thighs there was a distinctly punctiform mottling, while over the adductor aspect the mottling was retiform. It did not fade on pressure. The trunk was quite free from any erythema or mottling. In the course of four days the eruption had completely faded, and the patient was dismissed on Dec. 25th.

The cases which proved to be scarlet fever may be dismissed with the remark that the certifying practitioner having seen the case earlier had probably more definite and specific signs on which to found his diagnosis, Case 1 affording an example of this. We would call attention to Case 2; in this patient no desquamation was observed, though the child suffered from well-marked scarlatinal sequelæ—viz., enlarged cervical glands, rheumatic pains in the joints, and albuminuria.

Of the cases of doubtful scarlet fever we give Case 3 as a fairly typical example. A brother admitted at the same time probably had scarlet fever. He also was considered doubtful at first, but was after a time transferred to a scarlet fever ward on account of desquamation on the legs. He was dismissed from the latter after five weeks' residence without having contracted scarlet fever.

As regards cases of tonsillitis no great difficulty is experienced when they occur singly in a family none of the other members of which are suffering from scarlet fever; but when they arise in a family in which one or more of the members are suffering from scarlet fever they are a cause of great anxiety to the physician in attendance. Attacks of this nature are considered by many authorities to be specific and infectious, and yet they do not seem to confer immunity on the person attacked. We have a good example of this in the family the case of one member of which is reported *in extenso* (Case 4). On the same day as Case 4 a younger brother was admitted. A day or two later an elder brother and a sister were also sent to the hospital. The history in each case was similar to that of Case 4, and on admission there was nothing observed but a tonsillitis. The sister and two younger brothers were transferred to the isolation ward on Dec. 7th, 1895, and were dismissed well on Jan. 1st, 1896, nothing having occurred to warrant the diagnosis of scarlet fever. The third brother was left in a scarlet fever ward, and after twenty-six days developed a typical attack of scarlet fever. Similar cases with a like sequel have been observed by ourselves and are doubtless familiar to anyone who has had charge of scarlet fever wards for some time. We have classified such cases under the heading of tonsillitis, though one might be justified in considering them as cases of aborted scarlet fever. The class of non-specific eruption includes, besides the case of which a synopsis is given above, one case of urticaria and two where an erythema of an indefinite character was present, but where neither the history nor the course of the case led to any reasonable suspicion of scarlet fever.

Of the unclassified cases, one patient was hysterical and the other was sent in from a public institution along with another child who was suffering from scarlet fever. She, however, neither had that disease on admission nor did she contract it.

Glasgow.

ILLUSTRATIVE CASES OF APHASIA.

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

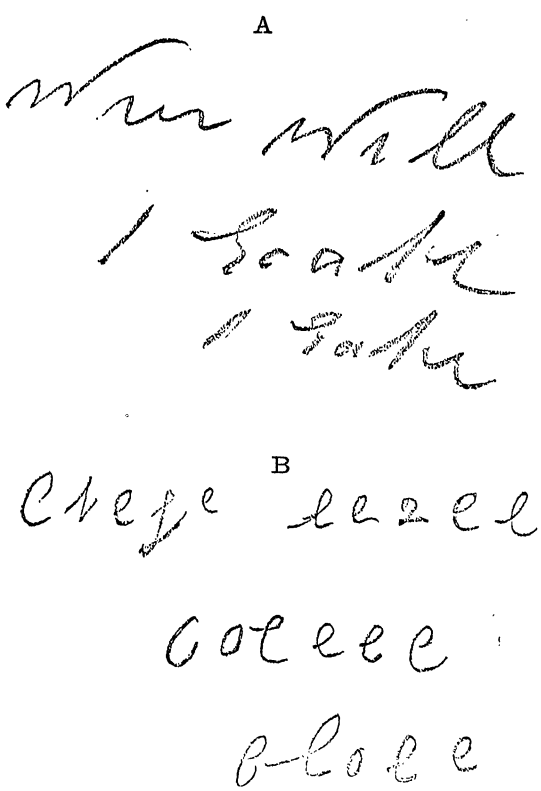
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

(Continued from p. 871.)

CASE 3.—*Complete word-blindness and marked agraphia; no hemianopsia; partial recovery; second cerebral attack followed by complete word-blindness, marked agraphia, and right sided homonymous lateral hemianopsia; post-mortem examination; large lesion (softening) in the white matter of the left occipital and parietal lobes; the left angular gyrus intact; softenings in the right hemisphere, cerebellum, &c.*—In the following case the patient was suddenly seized with giddiness and mental confusion, but no loss of consciousness. In this state of mental confusion he mistook lead pencils and spectacles for money. This condition was followed by paraphasia, word-blindness and agraphia, and some loss of power in the right hand. When I first saw him, some eight months after the original seizure, he was almost completely word-blind and almost totally unable to write; his memory was defective, but he could understand everything which was said to him and could speak perfectly. From this condition he slowly recovered. Three months afterwards he had a second cerebral attack. The word-blindness and agraphia again became almost complete, and right-sided homonymous hemianopsia was now developed. I am consequently disposed to think that the lesion, which in the first instance had, I supposed, involved the left angular gyrus (visual speech centre), had extended more deeply into the white matter and invaded the optic radiations of Gratiolet. In this localisation I was mistaken, for the post-mortem examination showed that the cortical grey matter (angular gyrus) was unaffected, the lesion being situated in the white matter of the occipital and parietal lobes. During the time which elapsed between the patient's first coming under my notice and his death there were several additional seizures, and the lesions found at the post-mortem examination were multiple. It is difficult in such circumstances to draw accurate conclusions, but the point of interest is that the visual speech centre itself did not seem to be directly involved, while the power of writing was markedly impaired. Other points of interest in the case are:—1. That

Hosted by Google

the patient, who was unable to read the words "hat," "dog," and "cat" written on the blackboard, did manage to read them (by the aid of muscular sense impressions) when he traced them over with chalk.[1] 2. That the patient could not name the letter "G," but when asked to name it said "George"—his own name. In other words, in this patient, as in some other cases of sensory aphasia which I have met with, the individual letters had in some degree lost their original significance and had (no doubt in consequence of frequent association and repetition) come to be associated with the names of things or with words. The condition is somewhat similar to that which was present in the next case, in which the patient could read words (combinations of letters), but was nevertheless unable to read the individual letters of which those words were composed. 3. That at my last visit the patient (who was not blind it must be remembered) was unable to name objects (a knife, pencil, and key) when they were shown to him—i.e., through the sense of sight—but was able to name them correctly (through the sense of touch and the muscular sense) when they were placed in his hand;[2] in short, a condition of optical aphasia, as French writers term it, was present.



The notes of the case are as follows:—A man, aged fifty-eight years, came to the out-patient department of the Edinburgh Royal Infirmary on Oct. 17th, 1891, complaining of inability to read and write.

Previous history.—His wife, who accompanied him to the hospital, stated that he had a "stroke" on Feb. 16th, 1891, and that he had been unable to read or write since. The late Dr. T. G. Balfour subsequently sent me the following interesting account of the manner in which the attack developed.

"I attended George —— about three years ago for an attack of articular rheumatism, but so far as I can remember there was no cardiac affection. I was again called to see him on Feb. 17th, 1891. For about a year previously he suffered from indigestion and occasionally from headache. For three or four days before the onset of the cerebral attack he had slight attacks of giddiness which, however, passed away in a few minutes. On Feb. 16th he felt pretty well and went out to pay his gas account. He accomplished this satisfactorily, but on the way back to his place of business he was seized with a peculiar sensation (which he could not fully describe), he was somewhat giddy but did not lose consciousness; he walked to his place of business in the Royal Exchange. He was a billiard marker, and when he entered the billiard-room and the intending players came to pay him fourpence each for a game he was aware that it was a sixpence or a shilling (as the case might be) which they had given him, but he could not give them proper change in return. He was so confused that he gave them lead pencils and even his spectacles, and when he gave money he gave more in exchange than was due, and the men returned him what he had given in excess. The men immediately saw that something was wrong, and he was told by his master to go home, which was only a short distance away. He scarcely knows how he reached home, but he knows that he staggered on the road, and his wife says that he was found climbing up the stair to his house on his hands and knees. When he came into his house he exclaimed, 'I am blind,' and fell down at the back of the door and vomited a good deal. After this he felt a little lighter and easier, and went to bed, but with his clothes on. His speech was then much affected; he had difficulty in getting the right word—e.g, he asked his wife to 'shut the gas' instead of 'door,' and so on, always substituting a wrong word for the proper one. I saw him the next day (Feb. 17th) and found him lying in bed, with a look of ordinary intelligence; he noticed me and recognised who I was, but was unable to articulate any word. On my asking if he had pain in his head he put his finger to the top of his forehead and rubbed it; he also indicated that he felt pain over his stomach. Mustard blisters were applied to the nape of the neck and over the stomach; aperient medicine was also administered, and the feet were ordered to be put into a mustard bath twice a day. The only other important symptom besides the aphasia which was present was an inability to grasp with his right hand. The sensation in the right hand was, however, intact. He had no prickling sensations or feeling of numbness in hands or feet or anywhere about his body. Notwithstanding his exclamation about blindness on reaching home, I could not detect any trace of loss of vision. His sight seemed normal, and his hearing also appeared to be natural. He continued for some days in very much the same condition. In the course of a week the power of the right hand returned and he very gradually regained the power of expressing himself, though he still continued to use wrong words. On testing his writing it was found that he could not form a single letter, he could only make marks. In about three weeks his speech was considerably improved, and he was able to sit up in bed and felt stronger. On the evening of March 7th, at midnight, he became excited and seemed very much confused. He called (as well as he could) for his clothes, put them on, and then immediately afterwards took them off, declaring that that was not what he wanted, calling for other portions of clothing, which he treated in like manner. This excitement went on from 12 till 4 A.M. (March 8th), and even at 8 A.M. he was still confused, thinking it was Tuesday when it was Sabbath. He gradually settled down again, and from that time progressed steadily, gaining more power of speech. I may mention that since the cerebral attack he has never suffered from dyspepsia in any form. My last visit was paid to him on March 24th."

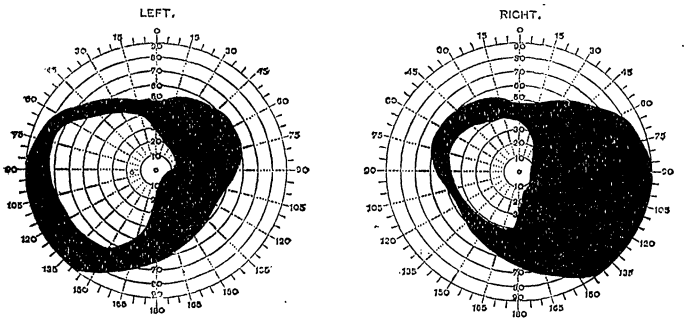
Present condition.—His general appearance was that of good health. There was no paralysis. The auditory and motor speech centres and the connecting fibres between these centres seemed to be unaffected. The patient seemed to understand everything that was said to him. His articulation was unaffected. He seemed to be able to say anything that he wished to say. He could repeat everything that he was told to repeat. But his memory was very defective; he often required to be prompted by his wife, but he then answered sharply enough. (If this patient had never learned to read and write there would have been nothing, with the exception of some slight loss of memory, to show at this date that he had sustained any severe cerebral lesion.) The patient was almost completely word-blind. The acuity of vision (after correction with glasses) was normal. There was no hemianopsia. He was unable to read the following word and sentence:—"dog," "Are you a fool?" He recognised some of the individual letters, but not all. He also made mistakes with regard to numbers and figures. He read the numbers 100 and 73 correctly; he said 54 was "45," reversing the figures; he was unable to read 85 and 62. There was no paralysis of the right hand; he could button his clothes and make fine movements with the fingers and thumb of the right hand quite well. The grasping power, as measured by the dynamometer, of the right hand was 95, and of the left 85. He wrote with great difficulty. He was asked to write his name and age. He stated his age wrongly, putting it down as "45" instead of 58. He was told to ask a question in writing. He wrote the following (see Fig. 6);

FIG. 6.

Spontaneous question written by G. —— (facsimile reproduction). A ("When will I get better?") was written on Oct 17th, 1891. B ("George ——, George, George") was written on Dec. 2nd, 1893.

I could not make out what he meant until I asked him to read it. He then said, "When will I get better?" His wife stated that he was a good speller and writer before the attack. The heart's action was quick, but there was no valvular lesion; the radial and temporal arteries were atheromatous. The urine was normal; it contained no albumin. A tonic was prescribed.

Subsequent progress of the case.—On Oct. 24th the patient



[1] Déjerine and Mirallié state that this is only possible when the lesion is outside the "zone of language"; in other words, in those cases of word-blindness in which the patient can write spontaneously, in which the lesion involves the tracts proceeding to the visual speech-centre and not the visual speech-centre itself.

[2] In other cases the patient is able to name the object (which he cannot name by the sense of sight) by the sense of smell or taste.

Hosted by Google

was again seen at the infirmary. He read better on that day than at the previous visit, and was less nervous. His wife said that he was distinctly better in other respects. He read the words "cat," "man," and his own name correctly. He also read correctly every number which he was asked to read. On Jan. 23rd, 1892, he was seen again at the infirmary. He was decidedly worse. He had had another cerebral attack a month previously. He complained of pain in the head, and vomited. Since that attack he had been much more confused, had been speaking much worse, and his reading and writing, which had improved somewhat before this last attack, had been much worse. There was very marked right-sided homonymous lateral hemianopsia, the fixing point being spared, with decided constriction of the peripheral portions of the fields (see Fig. 7). He was unable to read the words "dog" and "hat,"

FIG. 7.

Fields of vision in the case of G. —— on Jan. 23rd, 1892, showing right-sided homonymous lateral hemianopsia with considerable constriction of the sound (left) halves. The fixing point is spared.

but read the number 100 correctly. He said 49 was "29." He read the letters "a" and "h" correctly, but said "c" was "s." When asked to write "cat" he wrote "sot." He wrote "dod" for "God," and the letter "a" for "o." He wrote his name, but very indistinctly. When asked to write 50 he wrote first "too"; on a second attempt, "so"; on a third, "20"; and on a fourth, "50." When asked to write the word "Edinburgh" he wrote a scrawl which could not be read. On Feb. 12th in the sentence "The year-book of treatment for 1892" he read "The," "book," and "1892" correctly. The number 1892 was read without any hesitation as "one thousand eight hundred and ninety-two." He could not make out the word "year." "Of," he said, was "to," and "for" was "from." He said "treatment" was "arithmetic." When told this was wrong he made a second attempt, and said "remoted"; on a third attempt he said it was "touriments." When asked to read the individual letters composing the word "treatment," he read "t, o, c, n, o, r," but after going over the letters a second time he managed to read some of them. He was asked to write the following words and figures: "Edinburgh" (he took much time to do this), "Monday," "hat," "dog," "100," and "41." The result in each case was very unsatisfactory. On Feb. 27th the patient read a little better. He said: "I can see the letters better and can work it better in the mind too." He was unable to read the words "hat," dog," and "cat." When his hand was helped to trace these words with chalk on the blackboard he managed to read them, though he could not do so before. (This interesting fact was demonstrated before the students). He read his own name sharply, but was unable to read "Edinburgh," saying it was "g, o." He read the number 60 after long consideration, and read the number 9 all right; 57 he said was "79"; 34 was "39"; but he read 79 correctly. He wrote down correctly the following numbers to dictation: 101, 61, and 52. He wrote "1011" for 1000, "11" for 7, "10" for 9. On Dec. 2nd, 1893, the patient's reading and writing were decidedly worse. He read the letter "d" correctly, but this was almost the only letter which he could make out. He said "o" was *nothing*, and did not recognise the letter "o" even when it was named to him. He could not name the letter "G." He said it was "George." He could not read the words "dog" and "cat"—could not read them even when his hand was made to trace them on paper. He was unable to write his own name, but made an attempt. On Nov. 22nd, 1894, the patient was seen at his own house. He had not been able to come to the infirmary for several months. Soon after I last saw him he had had another comatose attack and was insensible for five or six hours. Since recovering from this his mental condition had been much worse. When I went into the room he looked quite bright, said he knew me, but had forgotten my name. At the end of the interview he said "Dr. Bramley." When asked where I had seen him before he said, "At the infirmary." His mental condition was evidently very much impaired and his gait was feeble. He had difficulty in coördinating the movements of the right hand. He was unable to take hold of a pencil held in front of him with the right hand, but could readily catch it with the left. The inability was not so much a want of power as a want of coördination. The right leg was very weak; there was distinct loss of power in the right leg as well as want of coördination. His hearing was unimpaired, and he seemed to understand almost everything that was said to him. He answered short questions correctly, and seemed to have no difficulty in articulation. He repeated short sentences quite correctly. He was totally unable either to read or write. He was unable to name a knife, pencil, and key when they were held up before him, but when he took them in his hand, and after he had felt them, he told me what they were—i.e., named them correctly. I heard nothing more of him for some months. His wife then came to the infirmary to tell me that he had died in the asylum at Morningside. It seems that a few days after my last visit he had had another and more severe cerebral attack. After this he became so much worse that it was decided to remove him to Morningside Asylum. Dr. Bruce kindly sent me the following account of the patient's condition at the time of his admission to the asylum, and of the lesions which were found in the brain after death.

Condition on admission to the asylum.—"George ——, aged sixty-two years, was admitted on Dec. 6th, 1894. Mentally he was unable to speak in reply to questions and did not appear to understand what was said to him. Physically he presented symptoms of gross brain disease. All the muscles of the body were more or less wasted, probably from disuse. The motor power in the arms was equal and of average strength. The left leg was much weaker than the right; the patient was unable to stand, always falling backward and to the left. The knee-jerks were both greatly exaggerated. The pupils were equal and reacted slowly to light. Swallowing was much affected. From the date of admission to April 17th he lay like a log, passing urine and fæces as he lay. He died on April 17th, 1895, apparently from exhaustion. I noticed that during the last week of his life he was at times quite blind or appeared to be so, but this condition was not permanent. I give these details as the case was under my care. The post-mortem examination was an interesting one, as the lesion appeared to be confined to the white matter, the grey matter externally being quite firm and apparently healthy. I enclose copy of the post-mortem notes."

Notes of the post-mortem examination.—"The necropsy was made on April 19th, 1895. The head only was examined. The brain weighed 46½ oz. The scalp was slightly adherent. The skull cap was somewhat thickened and greatly condensed, the diploe being absent. The dura mater was firmly adherent to the calvarium and slightly adherent by delicate fibrous bands to the pia mater at the tip of both temporo-sphenoidal lobes. The pia mater and arachnoid presented considerable general milkiness over the upper surface and sides of the brain. There was a small osteoid formation in the arachnoid near the surface over the left Sylvian fissure. There were some delicate fibrous adhesions to the dura mater over the tip of each temporo-sphenoidal lobe. Almost all the arteries were very atheromatous. In the cerebrum there was a large depression extending over the whole of the posterior half of the upper surface of the left hemisphere. There was some general atrophy of the cerebral convolutions. The external configuration of the brain as a whole, as regards complexity of convolutions, shape, &c., presented no marked change. The grey matter in the first section made above the lateral ventricles was slightly pigmented, of a faint yellow colour, and somewhat

Hosted by Google

soft; it was perhaps somewhat atrophied and its layers perhaps blended. Scattered through the white matter at this level were numerous, somewhat soft, slightly yellow nodules with ill-defined outlines, mostly about the size of a pin's head, though some were somewhat larger, others smaller. There was a large area of old softening in the left hemisphere; it involved the white matter only of the occipital lobe and the posterior half of the parietal lobe. It was situated above the level of the ventricle, the roof of the posterior horn of which formed its floor. The surrounding grey cortex was practically intact, the softened white matter, however, extending almost close up to it. The softened tissue had a gelatinous appearance and was of a bright yellowish-brown colour. In the centre there was an irregular cavity containing fluid. There was a similar softening containing fluid in the external capsule on the right side. Scattered throughout the brain there were some small rounded deep red points which were probably miliary aneurysms. In the right hemisphere, in the corresponding position to the large softening described above, there was a diffuse area of softened tissue which, however, presented the normal colour. There was also much general softening of the ventricular walls, especially posteriorly. In the grey cortex of the right hemisphere in the parietal and occipital lobes some small areas of atrophic softening were found. The lateral ventricles were much dilated; the internal lining membrane of the ventricles was not thickened, and there were no granulations. In the white matter of the right lobe of the cerebellum there was a softening, similar to that in the external capsule, about the size of a hazel nut. In the convolutions of the left lobe on its superior aspect there was an area about the size of a horse bean, which, while preserving the normal markings, was firmer and darker than the surrounding tissue. On cutting across the pituitary body fluid spouted out of the ventricles. The medulla oblongata appeared to be normal."

Corrigendum.—Case 2, page 868, eighteenth line from the foot, instead of "was an example of cortical," read "was an example of subcortical."

DIPHTHERIA OF THE UMBILICUS.

BY BERNARD PITTS, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

ON Feb. 20th a child, aged fourteen days, was admitted into the Hospital for Sick Children, Great Ormond-street, under my care for inflammation of the umbilicus. The cord had separated on the eighth day and the resulting wound had continued to discharge extremely offensive pus. When seen on the 20th there was a brawny-red indurated area round the umbilicus of about the size of a five-shilling piece, from which the epidermis had peeled. The umbilicus itself was the seat of a dirty coloured wash-leather slough, discharging extremely offensive pus from an opening into which a probe could be passed for about an inch. The child's condition was otherwise good, the only other point of interest being an occasional inspiratory crow and with this some slight cyanosis. No definite history was obtained till the next day, when it was ascertained that a brother of the patient had been removed to a fever hospital for diphtheria during the previous week and had died on the same morning as that on which the history was taken (Feb. 21st), and that the mother was then an inmate of University College Hospital, where, on inquiry, it was found that she was suffering from diphtheria. A culture was then made of the pus escaping from the umbilicus and examined on the 22nd, when the bacillus of diphtheria was isolated. In the meanwhile the child, who had suffered from several attacks of vomiting, had become considerably weaker and died on the evening of the 22nd. After death nothing abnormal was found in the larynx or pharynx, nor was the condition at the umbilicus found to extend to any of the deeper structures.

Harley-street, W.

EXTENSIVE SUBCUTANEOUS EMPHYSEMA COMPLICATING DIPHTHERIA.

BY J. SCHUTZ SHARMAN, M.R.C.S. ENG., L.R.C.P. LOND.,
AND
D. D'ESTERRE, M.D., B.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.

WE report the following case believing it to be both rare and interesting.

A boy, aged six years, was on Feb. 17th, 1897, taken ill with a sore throat and slight difficulty in breathing. The following day he had an attack of epistaxis, and on examining the throat the tonsils were observed to be the seat of patches of exudation. There was a slight rise in temperature and pulse-rate, the dyspnœa being now characterised by noisy inspiration, the patient in general condition getting worse. The glands under the jaw were slightly enlarged, and the urine contained a considerable amount of albumin. Some of the exudation obtained from the tonsils was sent to the School of Preventive Medicine for bacteriological examination and the diphtheria bacillus was isolated. On Feb. 22nd subcutaneous emphysema appeared at the root of the neck, giving rise to the characteristic fine crackling feeling, and forming tumours above the sternal end of each clavicle. During the next day the emphysema spread upwards to the submaxillary regions and downwards over the chest, and in a few days air could be felt under the skin all over the trunk, but more marked on the right of the middle line. The right half of the scrotum was much inflated with air and was quite transparent. Subsequently the emphysema reached as far as the zygomatic regions above, while below the affected area was limited by Poupart's ligaments and the scrotum in front and by the margins of the coccyx and sacrum and the iliac crests. The child's temperature rose to 100° F., the pulse to 144 per minute, the dyspnœa became more urgent, and there was moderate cyanosis of the face. Coughing occurred frequently with semi-purulent expectoration, and rhonchi were heard scattered throughout the lungs. Shortly before death the thermometer registered 101·6°, the pulse reached 180 per minute, and the urine contained one-third albumin. The treatment consisted mainly of stimulants, iron, antiseptics, and the use of the steam kettle and tent. The dyspnœa did not seem at any time sufficiently urgent to necessitate tracheotomy. A post-mortem examination limited to the neck was all that could be obtained, and this was just sufficient to eliminate the possibility of ulceration or perforation of the trachea as a cause of the emphysema. The trachea and larynx were found to be lined with false membrane.

Remarks.—We regret that owing to the difficulty in obtaining permission to perform a complete necropsy the cause of the emphysema could not be ascertained. Such a condition of almost universal emphysema complicating diphtheria is seldom met with, we think, though we are aware of a limited emphysema occurring in the neck after tracheotomy and in some cases of pulmonary disease where it has been traced to the rupture of an air vesicle. We think in this case the probability is that the emphysema occurred through the rupture of an air vesicle and the escape of air into the adjacent tissue of the mediastinum and thence to the neck and trunk.

EXPERIMENTAL DISTORTION.

BY W. S. HEDLEY, M.D. EDIN., M.R.C.S. ENG.

THOSE who use the x ray paper or other flexible sensitised surface in radiography for surgical purposes must beware of producing artificial deformities. Shadows must be thrown upon a flat surface, not upon a curving one. The latter kind of distortion is easily realised by anyone who watches his own shadow lengthening and shortening as he walks across the "ridge and furrow." It is obvious that the sensitised

Hosted by Google

paper should not be adapted to the contours of the body. This would make the radiograph hopelessly misleading to the surgeon who works by it. It is true that the latter, in "locating" by means of a radiograph a foreign substance in the thicker parts of the body, does so by inference, and this is difficult enough; but inference carried to the extent

Distorted image of a normal leg.

in question would be simply bewildering. Imagine the surgeon confronted with the above example of experimental distortion produced by the simple but very misleading process of adapting a sensitised surface to half the circumference of a normal leg!

Mansfield-street, W.

PERMISSIVE VERSUS COMPULSORY PURCHASE.—For some time the Southampton Corporation has been promoting a scheme for the purchase of the property of the South Hants Waterworks Company. The corporation already possesses works supplying the old borough, but wished to acquire this company's business, apparently with a view to lessening the rate in portions which have recently been added to the borough and making one uniform charge for water for the whole area. The Bill, however, has been wrecked in Committee of the House of Lords. The ratepayers were given to understand that if, after the promotion of the Bill, satisfactory terms could not be arranged with the vendor company, the corporation would be at liberty to withdraw. This line has been taken all along, and special care was taken to insert a clause in the Bill giving the corporation power to withdraw in case their overtures were not accepted. It was intended by the authorities immediately after the Bill had passed to treat with the company, and if without favourable result, they would not give the statutory notice to purchase which, having been given, would have bound them to buy out the company. It was apparently the difference between permissive and *bonâ-fide* compulsory purchase which led the House of Lords to throw out the Bill.

CHARING-CROSS HOSPITAL.

(1) CASE OF MULTIPLE OSTEOMATA UNDERGOING SARCOMATOUS CHANGES; AND (2) CASE OF FRACTURE OF THE ANTERIOR FOSSA FOLLOWED BY HEMIANOPSIA.

(Under the care of Mr. JOHN H. MORGAN.)

THE first case illustrates the change which sometimes takes place in a tumour of the bone which is of innocent nature at its commencement. It also shows the extremely painful progress of such a case when the surgeon considers that other complications forbid removal of the changed growth. The relief which would have been afforded to the sufferer by an amputation, could the surgeon have seen his way to its performance, and had the patient consented to it, would evidently have been very great. The second case is an example of a rare complication after fracture of the base in the anterior fossa. Many cases have been published showing the results of injury to the anterior part of the skull in the production of loss of vision, usually in the eye on the same side. There has been, however, far too great a tendency to ascribe the optic atrophy and blindness which follow such an injury to the extension of a fracture through the optic foramen and compression of the nerve by fragments of bone. Fracture through the optic foramen has been met with by Dr. Berlin[1] and others, but it is extremely rare. The degeneration of nerve is probably far more commonly the result of hæmorrhage or inflammation, or both combined, than of fracture and actual compression by bone. In fifty-four cases of fracture of the base[2] in no single instance was fracture revealed in the neighbourhood of the optic foramen; but in eight, where the fracture of the base was severe, blood was found extravasated in the sheaths of the nerves, and in one (at the end of eight days) there was slight neuritis. In one case also, where fracture of the optic foramen had been suspected when first under observation, examination of the case after death three years later showed that there had been considerable inflammation about the optic nerves affected, but no fracture near the foramen. We do not know of any specimen showing the fracture in our museums.

CASE 1. *Multiple osteomata undergoing sarcomatous changes.*—A man, aged fifty-five years, sought admission to Charing-cross Hospital in October, 1896, on account of pains in the right leg and thigh. He had observed varicosity of the veins of both legs for over ten years, but had never been inconvenienced by this till June, 1895, when an ulcer appeared on the lower half of the right leg, which lasted until the following September. Eczema followed, for which he was treated at St. Bartholomew's Hospital and which continued until November. The pains of which he complained then commenced. They were shooting in character, and started from the dorsum of the great toe and passed up the anterior and outer side of the limb as far as the region of the anterior superior spine. On admission the pigmented cicatrix of an old ulcer measuring about four inches by four and a half inches was observed on the antero-external and internal surfaces of the leg, and several irregularly tortuous superficial veins. In the region of Scarpa's triangle was a fairly firm ovoid swelling, slightly painful, not fluctuating or attached to the skin, which was not reddened. This gave no impulse on coughing, and was said to have first appeared about ten days previously to his admission. The patient stated that as long as he could remember there had existed several large bony tumours in each leg, which had never given him pain or inconvenience. These were situated (1) on the antero-external surface of the right femur; (2) in a similar position on the left femur;

[2] Battle: Lectures on Injuries to the Head, THE LANCET, July 12th, 1890, p. 63.

Hosted by Google

(3) on the internal aspect of the head of the right tibia; and (4) on the posterior surface of the middle of the left tibia, causing a large prominence in the calf. All these were firm, hard, immoveable masses, possessing no thrill, not attached to the skin, and with no eggshell crackling. The patient left the hospital at his own request, but was re-admitted on Nov. 15th, 1896, on account of increasing pain in the thigh and leg. On examining the patient in bed it was found that the veins which had a few days previously been prominent and varicose in the lower part of the legs, particularly the right, were no longer so, and the skin which had been slightly œdematous was normal, with the exception of the cicatrix above mentioned. A large irregular hard mass projected in the upper third of the tibial and fibular region, which was not attached to the skin but firmly fixed to the deeper structures and apparently connected with both bones. Over this region the skin was œdematous, and in the centre there was some area of fluctuation. Pain was constant and was aggravated by handling. The knee-joint appeared to be unaffected, but movement was limited on account of the bony swelling. The swelling in Scarpa's triangle did not appear to have changed. The lower part of the right thigh was two and a half inches larger in circumference than the left, and the upper part of the right leg measured two and three-quarter inches more than its fellow. The temperature varied between 98° and 101° F., and there was excessive pain in the swelling at the upper part of the right leg, aggravated at night. On Dec. 4th an incision was made over the swelling about three inches below the patella, and on introducing a finger a large bony cavity was found filled with soft granular débris. A second incision two inches behind the former and immediately in front of the fibula entered a similar bony capsule, from which masses of broken-down bone and large quantities of very soft gelatinous material, having the appearance of the degenerated contents of an enchondroma, were scooped out. The cavity was well washed out with perchloride of mercury lotion, a drainage tube was inserted, and a dressing of cyanide gauze was applied. The pain did not diminish after the operation and the temperature continued to vary as before, but it was soon apparent that the growth was spreading. The microscopical examination of the material removed showed it to consist of mixed spindle and round cells in a fibrillar matrix. The symptoms continued the same until Dec. 21st, when it was noted that the wounds were completely blocked with large fungating masses which confined the discharges, consisting of pus and altered blood-clots. These, when evacuated, gave off a very foul odour, which was diminished by the free use of Sanitas and iodoform. The growth spread rapidly downwards upon the fibular aspect, and the stench from the discharges was most offensive and could not be effectually lessened by disinfectants and charcoal poultices. The pain was excessive and emaciation advanced rapidly. On Dec. 29th it appeared that the growth had invaded the kneejoint, as it became terribly swollen and large purple veins stood out prominently in the superjacent skin. Huge bullæ formed on the peroneal aspect of the skin, which in some places commenced to slough, and the same condition was seen in the great toe. The pulsation in the posterior tibial could not be detected, and œdema was spreading upwards into the thigh. The situation of the pain did not alter, but it became more excessive. The patient grew rapidly weaker, but lingered until Jan. 3rd, 1897, when he died. Unfortunately, permission for a necropsy was refused.

CASE 2. *Fracture of the anterior fossa followed by hemianopsia.*—A man, aged twenty-six years, was admitted on Oct. 22nd, 1896, after falling from a ladder whilst cleaning windows. He was found to be suffering from severe concussion. The eyes were closed, the breathing was rapid, the respirations were shallow, the pulse was 120, feeble and frequent. On recovering from the acute shock he vomited about one pint or more of blood. He was then able to give his name and address and state where the accident occurred, but he remembered nothing about it. On examination there was great ecchymosis and swelling of the eyelids on both sides; there was no bleeding from the ears, but there was coagulated blood in the nostrils and a transverse fracture of the left patella. Two days later it became possible to examine the eye, and it was then seen that a subconjunctival hæmorrhage occupied the whole of the temporal side of the right globe, passing to the back. Both pupils were equal and reacted to light. On Oct. 31st the patient showed all the symptoms of cerebral irritation. There were marked subsultus, some pain in the right eye, and incontinence of urine. He wandered slightly, with intervals of consciousness, and the fingers constantly plucked at the bedclothes. The temperature varied between 99·4 and 101·6° F. On Nov. 3rd the temperature rose to 103·2°; he was very drowsy, but answered questions when roused. The tongue was very loaded and the breath extremely foul. The bowels were opened by purgatives and enemata. On the 6th the temperature was still high (101·6°), the tongue was still coated, and the breath very foul. He was very drowsy, but answered questions quite rationally. When dozing off his breathing became irregular and stertorous. There was some twitching of the muscles of the right angle of the mouth, but no movement of the left; the left nasal fold was less marked than the right, and he could not close his left eye. Subconjuctival hæmorrhage was still present, the pupils were equal and reacted to light, and there was slight conjugate deviation to the left side. The tongue was brown and dry, there were sordes on the teeth, and the breath was excessively offensive. The pulse was very irregular—one minute numbering 70 and the next 100, full and fairly strong. On the 9th the patient was better, the signs of facial paralysis had almost passed away, but when asleep there was still some slight twitching of the facial muscles of the right side. The deviation of the eyes had passed off. On the following day, the 10th, the temperature rose to 101·8° and the pulse to 120, small, weak, and irregular; the breath was still extremely foul, and the respirations were quiet. During the next four days the patient continued in much the same condition, wandering slightly in his talk, but answering questions. All facial paralysis had disappeared, but his speech was indistinct and guttural. On the 17th the temperature suddenly rose to 102·4° and the pulse to 140, small and weak. Swelling and œdema appeared over both eyelids and spread down to the cheeks, and a limited area of erysipelas attacked these parts, which lasted for eighteen days, during which time he was isolated. On returning to the ward when convalescent from this attack it was observed that a small fluctuating swelling existed over the orbital arch and just to the right of the metopic suture. This swelling was bounded by hard, elevated edges of bone, and in the centre was a fluctuating area, emphysematous, but showing slight pulsation synchronous with that of the temporal artery. The tongue remained very loaded and the breath continued to be very foul. At times the urine and fæces were passed unconsciously. On ophthalmoscopic examination of the eyes on Dec. 8th the discs were found to be very white, with very sharply defined edges, but no white streaks were noticed around the vessels, which exhibited no pulsation. The emphysematous crackling in the small swelling lasted from the 8th to the 14th, when it disappeared, leaving a small hard bony elevation, and there also appeared another small boss of callus under the inner third of the right orbital arch. On the 14th further examination of the fundus revealed that there were loss of vision in both temporal fields, paralysis of the nasal halves of both retinæ, and temporal hemianopsia. Dr. Mott, who kindly examined the patient, observed that he had seen the same condition in a case of acromegaly with enlargement of the pituitary body. This observation was of extreme interest when the probable line of fracture came to be considered. Dr. Mott found that the patient could not read even three large letters in succession easily and that he had considerable loss of memory. He found the discs very white and the vessels normal in size but rather curved, but he could observe no retinal changes. Very probably there was early optic atrophy. Dr. Mott added: "No doubt the morbid process is situated at the chiasma, damaging chiefly its central portion and affecting thus the decussating fibres from the nasal half of each retina. I should think, however, it has involved other fibres from the central portion as well." These conditions remained the same until Jan. 22nd, 1897, when the patient was sent to the Limpsfield Convalescent Home, his general health having much improved.

Remarks by Mr. MORGAN.—The history of Case 1 offers a fair presumption as to its nature. The bony tumours were without doubt of congenital origin, and the rapid sarcomatous change in that on the right tibia is certainly an unusual pathological development. The question of amputation of the thigh was considered, and would have been proposed but for the large mass of growth in the upper part of the groin, which, although bearing some resemblance to an omental hernia, was almost certainly a mass of secondary growths in the glands, which became affected before the

Hosted by Google

evidence of malignancy became apparent in the original growth. The line of the fracture in Case 2 can only be indefinitely surmised by the course of subsequent events. That the base of the skull was fractured in the anterior fossa was indicated by the ecchymosis of the eyelids with the subconjunctival hæmorrhage; and that there was rupture of the mucous membrane, either in the nose or in the upper part of the pharynx, was proved by the large amount of blood which was vomited soon after the patient's admission. It was probably through this lesion that the septic material spread which gave rise to the subsequent erysipelas, and the inflammatory products may have been the causes of morbid effects upon the chiasma and even the pituitary body. The emphysema noticed in the swelling over the frontal sinus was probably the result of decomposition, since the patient was unable by any effort to force air into this swelling. Subsequent inquiry elicited the fact that the patient had as a child been subject to fits, but had not suffered from any attacks since early infancy; his memory had never been good, and on account of the fits he had never learned to read or write. His eyesight seems to have been defective previously to the accident, but it has been very much worse since, and his memory is now so feeble that he cannot remember a name for two minutes together. The patient has been placed under the observation of Dr. Mott, who will watch and report any further developments.

HEREFORD GENERAL INFIRMARY.

A CASE OF PARTIAL RUPTURE OF THE SPINAL CORD WITHOUT FRACTURE OF THE SPINE; NECROPSY.

(Under the care of Mr. R. THOMASON.)

THIS case is a most unusual one and may prove of considerable importance from a medico-legal point of view, as it establishes the possibility of rupture of the spinal cord without any fracture of the bones containing it. The points of chief interest are indicated in the remarks appended to the case. For the notes of the case we are indebted to Mr. A. M. Watts, house surgeon.

A man, aged sixty-five years, while driving from Hereford to his home on Jan. 2nd, 1897, fell out of his cart. He was partly under the influence of drink at the time, but picked himself up and walked as far as his residence, a distance of a mile, put his horse away, and then sat down in a chair by the fire. Some time afterwards (three hours from the time of the accident) he noticed that he had no power in his right hand, then that his left hand was paralysed, and then that he could not move his legs; the paralysis came on so rapidly that it seemed to affect all his limbs almost simultaneously. On arriving home his neck felt a little stiff, but he had no pain in it. He had always been a healthy man and was not in the habit of drinking to excess. The patient was admitted to the infirmary on Jan. 4th. He lay in bed on his back and his respiration was entirely diaphragmatic. He answered questions rationally and had no cerebral symptoms. Movement of his neck caused pain. There was no bruising of the skin and no irregularity of the spinous processes. When he was lying still he had no pain in his neck or any pain in the course of the nerves. He could raise his arms from his sides to a horizontal position and could move them inwards across his chest; he could flex but could not extend his forearms; he had no movements of the hands or fingers. The knee-jerks and the plantar reflexes were absent. There was loss of all sensation of the trunk and the lower limbs below the level of the third costal cartilage; no hyperæsthesia was present above that level. There was also loss of sensation on the anterior and posterior surfaces of the forearms on the inner halves, on the whole of the dorsum of the hands, and on the inner part of the palms and on the palmar aspects of the little fingers. The patient had retention of urine and constipation. The chest was normal. The pulse was full and regular, being 56, and the temperature was sub-normal. The urine was acid, of specific gravity 1025, and contained a trace of albumin. No alteration in the amount of paralysis or anæsthesia was noticed and the patient's mind remained clear until his death, which was due to œdema of the lungs, and took place twelve days after the accident. The reflexes remained absent and the pulse slow. From the absence of any signs of fracture of the spine, and also from the absence of pain in the course of the nerves and hyperæsthesia, the injury was thought to be probably limited to the spinal cord. As the patient had absolute loss of the reflexes up to the time of his death a total transverse lesion was diagnosed, the seat of it being just between the origin of the sixth and seventh cervical nerves as the musculo-cutaneous and external anterior thoracic nerves escaped, while the musculo-spirals, medians (with the exception of their cutaneous branches) and ulnars were paralysed. The circumflex nerves were not paralysed, and although they come off with the musculo-spirals from the posterior cord of the brachial plexus, their fibres seem to be derived and also the cutaneous fibres of the musculo-spirals and medians from the sixth cervical nerves. As regards treatment, there was little to be done except to keep the patient's spinal column at rest, to prevent bed-sores, and to relieve the retention of urine by the passage of a soft catheter.

Necropsy.—The spine was exposed by a vertical incision over the spinous processes. No irregularity or signs of fracture could be detected, so the spinal canal was opened by removing the spinous processes and laminæ, but no hæmorrhage was found in it. The spinal dura mater was seen to be torn transversely across in its left half, so it was, together with the spinal cord, removed. On dividing the dura mater longitudinally on its posterior aspect the cord was exposed and the left half found to be torn across in the line of the wound in the dura mater, which extended round to the middle line anteriorly. An antero-posterior longitudinal section was then made of the spinal cord; at the seat of the rupture, and for a distance of half an inch above it, the cord was found to be very soft in consistence and greyish in colour, the limits of the grey area above being distinctly defined by a somewhat irregular transverse line; this condition of the cord apparently existed through its whole transverse section. On comparing the cord with the bodies of the vertebræ on its removal the rupture was seen to be exactly opposite the articulation between the sixth and seventh cervical vertebræ. A little movement could be obtained in this articulation, but the posterior common ligament was intact.

Remarks by Mr. WATTS.—As a rupture of the spinal cord is a somewhat uncommon accident, I think that it is worth while putting this case on record, especially as there was apparently no fracture of the spine, and although a little mobility between the sixth and seventh cervical vertebræ was found the posterior common ligament was not ruptured. The case is also interesting for the following reasons:—(1) After the accident the patient walked a mile and the paralysis did not come on until three hours afterwards; (2) because the paralysis on the one side of the body was exactly similar to that on the other; and (3) although there was absolute loss of reflexes, still the cord was not entirely divided. My thanks are due to Mr. Thomason, under whose care the patient was admitted, for permission to publish the notes.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Epidemic of Infantile Paralysis.—Gastrostomy for Swallowed Œsophageal Tube.—Removal of Cerebral Tumour.—Extravasation of Urine.

A MEETING of this society was held on March 26th, the President, Dr. BUZZARD, being in the chair.

Dr. PASTEUR read a paper on an Epidemic of Infantile Paralysis occurring among children of the same family. The epidemic was limited to this household. Every one of the seven children in the family was attacked in rapid succession within the space of three weeks with fever of moderate severity, accompanied by severe headache. In three of the children—aged eleven, nine, and five years respectively—paralytic symptoms supervened within seven days of the commencement of illness. The type of paralysis varied in the different cases. In one there was flaccid paralysis of the left arm; in another right hemiplegia with marked and persistent muscular rigidity of the arm and the leg, with more transient paralysis of the face and soft palate on the same side; whilst in the third case there was paralysis with rigidity limited to the left lower limb. In two more the primary fever

Hosted by Google

was followed by tremors lasting a few days, whilst in the remaining two the primary fever was not followed by any nervous disturbance. As regards the cause of the outbreak, it was possible to exclude the acute exanthemata, diphtheria and influenza. The points of resemblance to infantile paralysis were held to justify the diagnosis in spite of the remarkable characters of the paralysis. The cases prove that a poison giving rise in one instance to a paralysis indistinguishable from the acute atrophic paralysis of childhood is also able to determine lesions in other parts of the nervous system. They further strongly confirm the growing impression that infantile paralysis is an acute infective disease.—Dr. ORMEROD remarked on the difficulty of reconciling the symptoms with simple anterior polio-myelitis. It was true that the account of the febrile stage did not correspond with that usually seen in epidemic cerebro-spinal meningitis, but it was worth considering whether something of this nature would not account for the associated rigidity and pain left in the third case brought forward by Dr. Pasteur.—Dr. BEEVOR said that he had seen the cases when they were in hospital, and, though the first was clearly one of anterior polio-myelitis, the second was undoubtedly of cerebral type, and the amount and duration of the rigidity were in favour of the meningitis theory, but there was no pain. Except for the amount of rigidity the third case was like an ordinary one of infantile paralysis.—Dr. CAYLEY said that the cases were clearly instances of an acute specific fever. The term "infantile paralysis" was not always appropriate, and these cases showed that anterior polio-myelitis was inadequate, since there might be other lesions besides those in the anterior horns. If a satisfactory name could be devised it would greatly stimulate clinical work on the subject.—The PRESIDENT said that, so far as he knew, this was the first time that the infective character of infantile paralysis had been brought before the society. The cases showed that the toxic effects might not be confined to the spinal grey matter, but might affect the intracranial centres. He thought that the rigidity in these cases might possibly be due to the poison affecting the lateral columns. In his inaugural address last year he had drawn attention to the remarkable epidemics of infantile paralysis recorded by Medin, Bergenholtz, Colmer, and Cordier. He had himself seen a little boy affected with infantile paralysis whose sister a day or two previously to his attack had sickened with precisely similar symptoms, which, however, in her case cleared off without leaving her paralysed. Possibly if the disease could be recognised in the pre-paralytic stage it might be possible to cut the attack short by some mode of treatment allied to the antitoxin treatment.

Mr. C. B. LOCKWOOD read notes of a case of Malignant Stricture of the Œsophagus treated with Symonds's Tubes; Safety String Swallowed; Gastrostomy. The patient was a man, aged sixty-five years, who, whilst wearing a Symonds's tube for a malignant ulcer of the œsophagus, swallowed the string. Every effort to extract the tube failed. Inasmuch as only liquids could be swallowed in small quantities, and he was rapidly becoming thinner and weaker, the question of œsophagotomy or gastrostomy was debated. It was determined not to perform œsophagotomy because it was uncertain whether the tube was still in the œsophagus, and also whether the stricture was still safely permeable. Gastrostomy was performed and gave much relief. Three weeks afterwards the malignant growth perforated the trachea, and the man died from broncho-pneumonia. Afterwards the tube was found in the stomach, but had probably only escaped into it a few days before death.—Mr. CLUTTON thought that Symonds's tubes were a great advance on previous instruments at the time they were invented; but at the present day, when the mortality of gastrostomy had been so greatly reduced, he thought that it was the most useful form of treatment for malignant stricture of the œsophagus. The presence of a tube was apt to increase the amount of ulceration, and many patients could not tolerate its presence.—Mr. MAKINS asked if any attempt had been made to push the tube down by inserting a new and therefore stiffer tube. He could not speak with the same amount of enthusiasm with regard to gastrostomy in these cases as Mr. Clutton had done.—Mr. LOCKWOOD, in reply, said that no attempt had been made to push the tube down because it was such a large one. Patients were not always comfortable after gastrostomy, owing to leakage of gastric juice or to pain, one patient having so much discomfort that she insisted on the operation wound being allowed to close.

Dr. WASHBOURN and Mr. ARBUTHNOT LANE described a case of Tumour of the Brain which had been Successfully Removed. The patient, a woman, aged forty-six years, was seized with a fit on May 4th, 1896. It commenced as a convulsive twitching of the thumb of the right hand. This extended to the forearm and to the upper arm, the elbow being forcibly flexed. The leg on the same side was then similarly affected, the knee being bent. She did not lose consciousness. After the fit she noticed that her right arm and leg were weak and that the right side of her lips and tongue were numb. During the interval that preceded her admission into Guy's Hospital on Aug. 27th, 1896, she had a similar fit about every fortnight, the date of the fit corresponding to her menstrual periods, which were very frequent. She gave no history of headache or of vomiting. On admission her right side was found to be distinctly weaker than the left. During the time she was under observation she had fits similar in character to those already described. As she did not improve under anti-syphilitic remedies it was decided to explore the motor area of the brain on the left side. On Sept. 18th a large area of bone was removed and the dura mater, which was healthy, exposed. On the following day she had two fits. On the 21st the dura mater and arachnoid were divided, when a tumour was exposed. It grew from the pia mater and deeply indented the brain immediately in front of the upper limit of the fissure of Rolando. The tumour was sharply defined and shelled out readily. Though not invading the brain substance, a minute portion of grey matter was found adhering to its under surface. The longest diameter of the growth was from before backwards, where it measured about two inches, while its transverse measurement was about one and a half inches. Its depth appeared to equal its breadth. The convolutions depressed by it comprised the upper portion of the precentral gyrus, the adjacent area of the first frontal gyrus, with part of the second frontal gyrus, the marginal gyrus, and probably to some extent the gyrus fornicatus. Aphasia with paralysis of the right arm and of the right side of the face followed the operation. The aphasia soon disappeared. When she left the hospital, on Jan. 24th, 1897, she had complete motor paralysis of the right hand and forearm, with impaired sensation in the fingers. She had lost the pain in her arm which existed previously to the operation and which was temporarily increased by it. The facial paralysis had also disappeared. She had no recurrence of the fits after the removal of the tumour. At the present date (March 26th, 1897) movement is returning in the fingers, but the rest of the arm is still paralysed.—Dr. JAMES TAYLOR said that it was very curious that there was no affection of the leg with a lesion in this position. He thought that the loss of sensation confined to the forearm indicated a lesion of the cortex rather than of the internal capsule.

Mr. RICHARD BARWELL related a remarkable case of Extravasation of Urine in a man, aged thirty-six years, who previously to Nov. 24th, 1896, was perfectly healthy. On that night after coitus, in which nothing unusual occurred, he went to sleep, and on waking next morning found the scrotum much swollen; during the next few days the swelling increased, and, although feeling perfectly well, he sent for Dr. Nix on the 27th. On the 29th Mr. Barwell saw the patient in consultation. He had a subnormal temperature and a rather feeble, quick pulse, 108; the tongue was slightly furred, and the constitutional symptoms were slight, and he said he felt quite well up to four hours ago, and even now only "a little down." The scrotum was greatly distended, boggy to the touch, red, and studded with blotches here and there of dark-brown discolouration; the penis was but slightly swollen or reddened and free from sloughy spots; the perineum was much distended to within a very short distance of the anus, and exhibited two sphacelated spots. He asserted that he never had any difficulty in passing urine, which flowed in a full-size stream. With Dr. Nix's sanction Mr. Barwell made deep incisions in the perineum and scrotum, exposing the superficial muscles of the urethra and the testicles. The sodden tissues were full of urine with the usual ammoniacal, sloughy odour. One bleeding vessel, being too rotten to bear either torsion or ligature, was secured by leaving on it a pair of forceps; the very soft state of all tissues rendered interference with the urethra unadvisable. Five days after the incisions were made the patient lost about four ounces of blood by the rupture of a vessel in or close to the right testicle. This depressed his health considerably, but freer stimulation overcame the condition in

Hosted by Google

about eight hours. The rare and interesting features of this case lie in the local condition. Rupture of the urethra as an immediate result of coitus has once or twice been reported, but invariably in the penile portion of the tube, never, so far as Mr. Barwell was aware, in the membranous part. A No. 12 catheter passed into the bladder without encountering the slightest obstacle, and the treatment for stricture of the urethra was therefore unnecessary. The man lost by sphacelus about four-fifths of the scrotum, but the parts healed, and the whole was quite sound exactly six weeks after, the testicles being enclosed in a new bag, which, though it looked tight, interfered neither with comfort nor function.—Mr. MAKINS thought that extravasation of urine without discoverable lesion was not so very infrequent. He questioned if coitus could possibly have produced it in this case, as there was no stricture.

EPIDEMIOLOGICAL SOCIETY.

The Prevention of Tuberculosis.

A MEETING of this society was held on March 19th, Mr. SHIRLEY F. MURPHY, Vice-President, being in the chair.

Dr. JAMES NIVEN (Manchester) read a paper on the Prevention of Tuberculosis. In reviewing the history of the subject he said that in 1865 Villemin not only proved by experiments the inoculability of tubercle, but showed a clear apprehension of the etiology of the disease in man and animals, especially its dependence on overcrowding and deficient ventilation. But Koch, by his demonstration of the bacillus and by his discovery in tuberculin, not, indeed, of a cure, but of an almost unerring means of diagnosis, at once perfected our knowledge of the pathology and etiology of the disease. G. Cornet showed the absence of infectivity in the dust of rooms and hospital wards where precautions were taken against the drying of the sputa and also proved the rapidly fatal action of light on the bacilli; on the other hand, he demonstrated the insignificance of so-called predisposition compared with the influence of overcrowding, dirt, darkness, and damp, and he demonstrated the necessity of prolonged and close association with tuberculous patients for the direct infection of healthy persons. The Registrar-General's statistics showed an enormous diminution in the mortality from phthisis and tuberculous diseases since 1850, but Dr. Niven feared that the improvement must be to a great extent more apparent than real, and explicable rather by changes in nomenclature and by errors of diagnosis than by sanitary progress. Recoveries from the earlier stages of tuberculosis were more frequent than was commonly supposed, the records of necropsies in hospitals at home and abroad showing traces of healed lesions in from 20 to 50 per cent. of persons dying from other diseases. Tuberculosis was very rarely, if ever, congenital. Boltz in 2576 necropsies of children failed to find the smallest evidence of tuberculosis in any under one month, but from the third to the sixth month 8·6 per cent., from this to the twelfth month 18·3 per cent, and in the following years about 30 per cent. were more or less tuberculous. The observations of Koch on rabbits and guinea-pigs, and of Bang and Sidaingrotzky on cattle, have established the fact that the young of tuberculous animals were always born healthy and that they remained so if removed from their parents immediately after birth. The early diagnosis of the disease was of the utmost importance in man and domestic animals alike, especially in the cow, whose milk was a potent factor in the spread of tuberculosis among children. The sputa of all patients with chronic coughs ought, therefore, to be examined; and tuberculin, one small injection of which can do no harm, is a still more certain test applicable in every form of the disease. Examinations of cows and of milk in Germany, Denmark, America, and in this country have revealed an alarming prevalence of tuberculosis, especially in town cowsheds and in large herds; but, as Bang had conclusively shown, the disease might be extinguished with no loss to the owner if all the herd were tested with tuberculin and if those that re-acted were entirely separated from the rest and either fattened for the butcher or kept for a time for breeding, their calves being promptly removed to the healthy stalls. The test should be repeated twice a year till no more reactions take place, and all new purchases should be treated in a like manner. It would be well if the managers of public institutions would require a certificate of the freedom of milk from disease, and if dairymen were encouraged to provide such milk especially for infants. Men suffering from tuberculous phthisis should not be employed among cows, for the danger of infection was mutual. The milk of tuberculous cows should not be given even to pigs unboiled, for they and horses were liable to the disease. Unless the disease were far advanced there was little risk in the use of the flesh as food if all the affected organs were rejected. The sputa of phthisical persons were the great vehicles of infection. They should always be expectorated into spittoons, the use of handkerchiefs should be forbidden, and workmen in factories and workshops should be provided with Dettweiler's pocket spittoon. Railway companies should prohibit spitting in carriages, and should supply the proper vessels for the purpose; similar rules should be enforced in lodging-houses, &c. Heredity in the strict sense was as improbable as it would be in the case of small-pox; it meant only a susceptibility to infection in persons who had narrow chests and feeble constitutions, or were prone to catarrhal affections, leading to abrasions of the mucous membranes, and favouring inoculation with the spores which in a sound lung would be quickly destroyed by the leucocytes and cells of the epithelium. The rooms and houses of phthisical patients should be frequently cleaned without the raising of dust, and should be periodically disinfected; this was especially necessary in so-called health resorts, which were often foci of infection, as statistics and clinical observation amply proved. Dr. Niven advocated notification, while admitting the difficulties consequent on the long duration of the disease and the failure of the scheme which had been tried for a time in Manchester. He concluded by describing the methods for safeguarding cows and the regulations for dairy farms and cowsheds prescribed by the sanitary authorities in Manchester, as well as suggesting a system of veterinary inspection and control which might be undertaken by the county councils.

Dr. RANSOME said that he would not treat the patient as a leper, but would rather improve his surroundings. He had shown that in a dark, close atmosphere the bacilli could be cultivated for a long time in the condensed moisture of a room, but that in clean, dry, sunny apartments they soon died out. He believed that the reduction in the death-rate was real, and that it was due to sanitary improvement.

Dr. HERON maintained that prolonged and intimate association was necessary for personal communication of the disease, as had been experimentally proved by Koch, and remarked that Kitasato had shown that guinea-pigs might often be infected by bacilli too enfeebled to attack man.

Dr. PAYNE, Surgeon-General MCLEOD, Dr. WILLOUGHBY, Dr. SEATON BUCHANAN, Dr. BULSTRODE, and Dr. GOODALL also spoke.

OPHTHALMOLOGICAL SOCIETY.

Adjourned Discussion on Retro-ocular Neuritis.

A SPECIAL meeting of this society was held on Feb. 24th to continue the adjourned discussion on Retro-ocular Neuritis, Mr. E. NETTLESHIP, President, being in the chair.

Mr. W. H. JESSOP referred to cases illustrating the origin of the disease in question in tooth irritation and in fractures of the orbit, where atrophy of the nerve followed in about a month. The forms of neuritis associated with disseminated sclerosis and locomotor ataxy differed from the foregoing in the peculiar bluish-white appearance of the papilla, but were indistinguishable in aspect from one another. Though the visual fields and appearance of the nerve remained unaltered in the latter, in about four years there was usually complete loss of light perception. Hysterical and diphtheritic cases recovered completely.

Mr QUARRY SILCOCK, referring to the frequency with which the axial fibres of the optic nerve were affected, added another possible explanation to the suggestions already made by Mr. Marcus Gunn. This was that near the optic foramen the axial fibres were furthest removed from the vasa vasorum, so that any interference with the blood current might be expected to affect this tract first. He demurred to the greater functional activity of the fibres or of the lymph-flow in this region predisposing to degeneration under the influence of pressure. He referred to cases of irregular diabetes in which the defect of vision was more marked than the colour scotoma, where the symptoms were referred by Sir W. Broadbent to high arterial tension, and in which with

Hosted by Google

lowered blood pressure the scotoma disappeared and the vision became normal. Subsequently indiscretion in diet led to the re-appearance of glycosuria, and it was a question whether the ocular symptoms were due to the direct action of a poison or of altered blood pressure on the nerve. Alcohol led to arterial sclerosis, and this to exudation from the vessels, producing transient œdema, which might account for the transitory character of the manifestations in the eye. He thought that, except in direct orbital inflammation and injury, the cause of the disease must be sought in general diseases like syphilis, gout, and rheumatism, and this would accord with the benefit derived from salicylate of soda and blisters in the cases alluded to by Dr. Hill Griffith.

Mr. HOLMES SPICER spoke of cases which did not improve, but in which the scotoma remained. They occurred in males beyond middle life, who were the subjects of sudden failure of vision, unaccompanied by pain and independent of assignable cause. There was some swelling in the disc, which was best observed by the parallactic movement and apparent constriction of vessels. The use of tobacco had been quite moderate in these cases. Usually, failing to improve, they ceased to attend until the other eye began to fail. There were commonly general symptoms, such as paralysis or mental hebetude, which came on later, indicating progressive degeneration of the nervous system.

Dr. RISIEN RUSSELL described the changes he had met with in the nervous system in a fatal case of disseminated sclerosis, which were identical in their naked eye and microscopic appearances in all parts, including the optic nerve and tract, though it was not possible to say whether they originated in the nerve elements or the interstitial tissue. The changes in the optic nerves were advanced, both being completely destroyed in front of the chiasma, and there were extensive areas of degeneration in the optic tracts, but strangely enough there were districts of undestroyed fibres between. Optic nerve changes were more common in disseminated sclerosis than Dr. Gowers seemed to allow, but the visual defect was often transitory at first, whereas in tabes it was permanent. The patient in question had come under notice twenty-five years before with paralysis of both legs, when there occurred sudden complete blindness with inability to move the head, recovery occurring in two days from all the symptoms except the loss of vision in the right eye, which was permanent. On admission to the hospital there were symptoms indicating postero-lateral sclerosis. In the right eye there was bare perception of light with faint reaction of the pupil. The vessels appeared to be normal, but there was atrophy of the disc. He died from what appeared to be a sudden myelitis of the upper part of the cord, though there was no evidence of this at the necropsy. There was postero-lateral sclerosis, and in the cranium the dura mater was adherent behind the foramen opticum, binding down the nerve, which was consequently torn in removing the brain. This right optic nerve was destroyed from the eyeball to the chiasma and flattened.

Dr. MACNAUGHTON JONES said that these cases might be regarded either from a clinical or pathological standpoint. He had never seen a permanent scotoma result from frequent attacks of migraine, as had been mentioned by Mr. Cross. The cases he had met with were characterised by aberrations in the colour field with variable changes in the disc, these being sometimes absent, the symptoms being limited to one eye. Complications were rare and recovery was general He attributed the condition to poisons such as alcohol, tobacco, syphilis, gout, or to grief, mental worry, or eye strain, but he had not encountered it after febrile diseases. Cases dependent on functional changes were probably temporary and those due to organic lesions permanent.

Mr. ADAMS FROST quoted thirteen cases of acute retro-ocular neuritis in which the loss of vision occurred in from one to three days and amounted in some to loss of perception of light. Three only were bilateral. There was hyperæmia of the disc and in some papillitis two days later. The prognosis was good, all the cases recovering, seven completely.

Mr DOYNE, after eliminating instances which might be due to tobacco and other assignable causes, selected eighteen cases, which he divided into binocular and monocular varieties. Of these, the former included eleven patients in whom there was but slight sign of inflammation in the fundus, and of whom only two fully recovered. Of the seven monocular instances five were in women. There was more evidence of optic neuritis, and all recovered.

The PRESIDENT said the term retro-ocular neuritis no doubt covered many clinical conditions, and it was evident that in the present discussion cases of widely different nature had been described. He selected 120 cases which he divided according to their clinical aspect into several groups. 1. Monocular and idiopathic included the smaller number, which all recovered. 2. Cases ranging in age from sixteen to forty years, probably syphilitic, of which thirty-eight were females and sixteen males, all of whom recovered and exhibited no general nervous symptoms. (The symptoms in some of these cases were probably due to gummata of the nerve.) 3. Nineteen cases, including eight men and eleven women, thirteen of whom were aged over forty years, who did not recover and in whom the pain at the onset was more intense and lasted more than four days. 4. Five cases, three men and two women, in whom vision failed in both eyes at short intervals, one attack overlapping the other, followed by slight pallor of the discs and complete recovery, the ages ranging from twenty-three to thirty-five years. 5. Cases of disease of the general nervous system, chiefly disseminated sclerosis and locomotor ataxy, in which both eyes failed at longer intervals, the disc ultimately becoming sclerosed. Other cases were probably connected with disease of the teeth or of the sphenoidal sinus.

The discussion terminated with the replies of Mr. MARCUS GUNN and Dr. BUZZARD, who had introduced the subject.

HUNTERIAN SOCIETY.

Cerebellar Tumour.—Mental Disorders of the Climacteric Period.

AN ordinary meeting of the society was held at the London Institution on March 24th, the President, Dr. G. E. HERMAN, being in the chair.

Dr. HINGSTON FOX showed a case of Cerebellar Tumour (?). The patient was a woman, aged thirty-four years. She had a staggering gait, weakness of the right-hand grasp, and double optic neuritis. There was no spasm of the muscles of the back or conjugate deviation of the eyes. Weakness and pains in the legs, with vertigo and headache, began a year ago. Phthisis was present in the family.—Remarks were made by Dr. F. J. SMITH.

Dr. WILLIAM RAWES read a paper on Mental Disorders of the Climacteric Period. He first pointed out that medical men are frequently consulted at this period about symptoms which are the precursors of mental disease, and that the climacteric period is liable to considerable variation as to the age at which it appears and also as to its duration. In 56 cases the average was just under forty-seven years. Most women suffer from some form of neurosis at the climacteric, and any physical malady is liable to be aggravated, whilst many women are brought dangerously near the brink of mental disease; still, it is doubtful if the menopause is sufficient to determine an attack. Heredity is a potent factor in the production of insanity; it was traceable in 48 per cent. of the cases. The prospect of recovery is not so gloomy as supposed. Previous attacks from whatever cause render the menopause a source of great risk. Alcoholism is another factor. The prognosis is much more favourable when the alcoholism has been a phase in the insanity and not a habit indulged in for years. Grief and mental anxiety are the most common causes which produce a rapid onset of insanity at this period, whilst remorse is a frequent cause of the restless cases of melancholia. Worry caused by pecuniary losses is a contributing factor, but the most important, on account of its bearing upon treatment, is a combination of circumstances which may be termed "isolation with introspection"; its influence was traceable in 80 per cent. of the cases. This occurs especially in women who, having led active lives, have then little to do They examine themselves and their feelings as it were with a microscope, so that there is scarcely any limit to the number and variety of delusions produced in this way, which in the religious type tend nearly always to become suicidal. In some cases there has been found a history of irregularity and excess in menstruation. Melancholia is by far the most common character of mental disease at the climacteric—it occurred in 60 per cent. of the cases; 25 per cent. had mania, 15 per cent. delusional insanity, 46 per cent. showed a suicidal tendency; there were hallucinations of hearing in

Hosted by Google

50 per cent., of taste in 13 per cent., of vision in 26 per cent., and of smell in 10 per cent. About 50 per cent. of the patients recovered. Treatment consists in change of environment, open-air exercise, diet, electricity or massage, and tonics. The patient should also take up some form of congenial occupation. If delusions lead to attempted suicide the patient should be certified; but when this is necessary she should be told in a perfectly candid manner why it has been done. Deception practised on patients is harmful and wrong from every point of view.—Dr. SAVAGE agreed as to there being no special form of climacteric insanity, but rather a distinct grouping of symptoms which may precede, accompany, or follow the menopause. Symptoms following surgical removal of the ovaries are often only exaggerations of ordinary climacteric symptoms. There is a deadness or visceral anæsthesia in these cases, and where there has been puerperal insanity the menopause is a source of great danger. The symptoms associated with the climacteric are often hysterical and chiefly show the form of "rages," such as swearing. The symptoms of isolation and introspection may be termed "widow's disease." Travelling is not suitable in many cases.—Dr. J. F. WOODS stated that the most important agent in treatment is sleep, and that hypnotism is useful in melancholia.—Remarks were made by Dr. ROBERT JONES.—Dr. RAWES replied.

LIVERPOOL MEDICAL INSTITUTION.

Calculus in the Ureter.—Plastic Operation for Lupus.—Malaria in Central Africa.—Excision of the Rectum.

A MEETING of this society was held on March 25th, Dr. RICHARD CATON, President, being in the chair.

Mr. LARKIN read a note on Calculus in the Ureter. In cases in which operation was performed for stone in the kidney, and where no stone was to be found in the kidney, he was in the habit of turning the kidney out upon the loin and examining the whole length of the ureter by passing a probe along it into the bladder. On three occasions he had by this means detected a stone in the ureter.

Mr. ROBERT JONES showed a case in which a Plastic Operation for Lupus had been performed. The patient had been subjected to twenty-five operations without permanent benefit. Mr. Jones excised the lupus, carefully avoiding the facial nerve and Stensen's duct, and reflected a large flap from the front of the neck. This was adapted to the raw surface occasioned by the removal of the lupus. The edges of the skin incisions in the neck were then brought together. The result was very satisfactory.—Mr. PAUL mentioned that he had successfully covered the back of the hand, from which he had removed a large patch of lupus, with a Tagliocotian flap from the abdomen.

Mr. STANLEY KELLETT SMITH read notes of certain clinical points in Malarial Fever which presented themselves during an exploration of the country west of Lake Nyassa. There were under observation ten white men and about 700 blacks. It was found that among men on the march there was a close connexion between fairly rapid alterations of level and the occurrence of malarial manifestations. Whenever the route lay across level or gently sloping country fever was rare, but quick change from high veldt to low veldt and *vice versâ* was always marked by a great increase in the number of attacks. This point was illustrated by fever maps of white members of the expedition and by a sectional survey of the main line of march. Mr. Smith supported the probability of gradually acquired immunity, and drew attention to the prophylactic value of small daily doses of quinine in the form of the neutral sulphate sufficient to cause slight aural disturbance.—Dr. BUCHANAN, Dr. CARTER, Dr. A. DAVIDSON, Dr. ARCHER, and Dr. G. JOHNSTON took part in the discussion.

Mr. PAUL read a paper on a Second Series of Fourteen Cases of Excision of the Rectum. Two were for syphilitic stricture two for villous tumour, and ten for cancer. Short lengths of bowel were excised by the perineal and vagino-perineal incisions when the disease was situated in the lower third, and by a posterior median proctotomy when in the middle third. For extreme excisions a sacral flap was employed. The best results were obtained after removal of a short length of bowel by suture of the upper to the lower end. Approximation after extensive excision was considered bad practice, being more dangerous, and little, if any, better in result than when the stump was brought out and attached to a glass tube. The four non-malignant cases were cured. Of the malignant cases two died from the operation, two since from recurrence, and the remaining six were under observation. Of the previous series of fourteen cases, all malignant, three were cured (one of these having been watched for ten years and the other two for four years). A fourth was probably well, but could not now be found. Two died from the operation, and the remaining eight all died from recurrence after an average period of two years.

MIDLAND MEDICAL SOCIETY.

Election of Officers.—Paræsthesia.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 17th, the President, Dr. A. H. CARTER, being in the chair.

Mr. J. W. Taylor was elected President for the ensuing session, Mr. Garner was re-elected treasurer, and Dr. Kauffmann and Mr. Christopher Martin were elected secretaries.

Dr. SHORT read a paper on an Unusual Form of Paræsthesia, marked by Feeling of Coldness and Numbness in the Legs. The peculiar alteration in sensation dealt with in the paper was entirely subjective and not associated in any of the cases with objective alteration in sensation, motion, or nutrition. Nine cases of this condition were cited. The patients were all men of ages varying from nineteen to forty-nine years. Complaint was chiefly made of a cold feeling, generally associated with numbness, over the front of the thigh, round the knee-joint, and down the back of the leg in the calf and heel. One or two of the patients also experienced the feeling down the back of the thigh and down the shin. The sensation was comparable to that produced by cold wet clothes placed next to the skin. In addition there was an irritable condition of the mind due to the presence of the abnormal sensation, and absent when the latter was in abeyance. The symptom was periodic, resembling in this respect neuralgia, and at certain times might be entirely absent. In all other respects the patients were apparently quite well. The faradaic brush applied to the legs gave immediate, though only temporary, relief. Antipyrin and gelsemium also gave some relief in one or two of the cases, but of the many other drugs that were tried none had any appreciable effect. The condition was considered to be one of neuralgia, with possibly slight neuritis in several of the most severe cases.

Mr. F. MARSH showed a girl, ten years of age, whose left upper extremity he had removed for a Sarcoma of the Head of the Humerus by inter-scapular thoracic amputation after Berger's method, the only departure being the division and forci-pressure of the supra-scapular artery prior to the formation of the flaps, leaving only the posterior scapular artery to be secured subsequently. Extremely little blood was lost, but there was considerable post-operative shock and restlessness. A rapid recovery was made, the wound healed by primary union, and the patient was up on the sixth day. The growth was an endosteal mixed-celled (spindle and myeloid) sarcoma.

Mr. MARSH also showed a man, sixty-three years of age, from whom a Papilloma of the Larynx had been removed by Thyrotomy. The epiglottis concealed the greater part of the larynx. An incision was made in the middle line of sufficient length to expose the thyroid cartilage above and the upper four rings of the trachea below. The crico-thyroid membrane and the thyroid cartilage were then divided, and a papilloma attached to the under surface of the cords at the anterior commissure was removed with forceps and scissors. There was but little hæmorrhage. The thyroid cartilage and the openings in the trachea and crico-thyroid membrane were closed with catgut sutures. There was no subsequent dyspnœa or other troublesome symptom. The greater part of the wound healed by primary union. The man could now speak without difficulty and his voice was fairly clear.

Dr. THOMAS WILSON showed: (1) A Fibro-myomatous Uterus, with the Ovaries and Tubes; and (2) a Fibroid, the

Hosted by Google

size of a Fœtal Head, removed through the vagina together with the uterus.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Porro's Operation.—Kolpo-panhysterectomy for Cancer.—Twisting of the Pedicle in Ovarian Tumours.—Exhibition of Specimens.

A MEETING of this society was held on March 19th at the Medical School, Sheffield, Mr. H. BRIGGS (Liverpool), the President, being in the chair.

Dr. KEELING (Sheffield) related a successful case of Porro's Operation. The patient was thirty-five years of age and had had two children. The first labour had been normal; there was no pelvic deformity. After symptoms of eclampsia this her second labour set it, and on examination no trace of the os or cervix uteri could be found; but later under an anæsthetic a dimple was made out representing the cervix. This was gradually dilated, when it was found that an opening had been thus made into the peritoneal cavity behind the cervix. Cæsarean section was at once decided upon, and eventually Porro's operation was performed on account of atony of the uterus and great oozing of blood. The stump was fixed in the lower angle of the wound. The operation was successful, the mother and child being exhibited.

Dr. RABAGLIATI (Bradford) related three successful cases of Kolpo-panhysterectomy for Cancer. The first patient was forty-one years of age, and had had fourteen pregnancies and fifteen children in twenty-three years. The os uteri was covered by a large patch of foul-smelling ulceration, the uterus being partly fixed; operation was only undertaken at the earnest wish of the patient and relatives. There was severe shock, but an uneventful recovery. Eight and a half months later there was a recurrence in the posterior part of the cicatrix. The second patient was twenty-eight years of age and had had three children. There was a history of syphilis. She had a cauliflower excrescence involving the whole of the cervix and encroaching upon the vaginal mucous membrane and fornices; the operation was successful, but recurrence was found in the posterior part of the cervix in the course of the tenth week afterwards. The third patient was thirty-nine years of age and had had three children. She had suffered for two years from pain and for eighteen months from watery, blood-stained, offensive discharges. There was a large patch of ulceration on the inner surface of the cervical canal occupying five-sixths of the circumference, and also on the outer aspect of the cervix. The uterus was moveable, but high up and difficult to reach. The bladder was accidentally opened by the anterior incision, although a male sound was in it as a guide, and was sutured. The patient did well until the eighth day after the operation, when she had a rigor; her temperature was 103·2° F., her pulse 160, and phlebitis of the leg supervened, with herpes about the lips and mouth. Ultimately she recovered, and so far has had no recurrence (ten weeks after the operation). All three cases were operated upon by Martin's method, and in all the microscopic report was epithelioma. Dr. Rabagliati gave an account of the anatomical considerations which make the prospect of non-recurrence of uterine cancer more favourable than in other cases of cancer.

Dr. SINCLAIR (Manchester) read a paper on Twisting of the Pedicle in Ovarian Tumours. The cases on which the remarks were based were four consecutive ovariotomies, and the object of the paper was chiefly to call attention (1) to the severity of the symptoms occasionally produced by torsion; (2) to some difficulties in the diagnosis; and (3) to the question of immediate operation. In all these four cases ovariotomy was performed without delay, and the result in each case was satisfactory.

Dr. HELLIER (Leeds) showed a Placenta from a patient who had suffered from hæmorrhages during the period of gestation. Premature labour was induced at the sixth month.

Dr. LLOYD ROBERTS (Manchester) showed a Cystic Tumour, the cavity of which consisted of the calyces of a cystic kidney.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Dilatation of the Stomach.—Relapse in Scarlet Fever.—Celandine in Cancer.

A MEETING of this Section was held on March 12th, Dr. G. F. DUFFEY, the President, being in the chair.

Dr. BOYD read a paper on the Significance of Dilatation in Functional and Organic Diseases of the Stomach.—Dr. DOYLE said that lung troubles, such as chronic bronchitis, were causes of partial dilatation of the stomach, on account of the passive congestion interfering with the nutrition of the organ. Another cause was the badly kept condition of the teeth of the poorer classes, and the short time given by them to the proper mastication of their food, which was usually of a starchy nature.—Dr. POTTER said that he had frequently found a large teaspoonful of vegetable charcoal taken an hour or two after meals very beneficial in the treatment of dilated stomach.—Dr. TWEEDY referred to a case which he had formerly shown where the stomach filled almost the entire abdominal cavity, this condition being due to the habitual eating of large quantities of potatoes. The pressure of the stomach filled with a large quantity of food of this nature, which cannot be got rid of as quickly as it ought to be, was one cause of constipation, and, moreover, a dilated stomach filled with starchy food could, by drawing down the pylorus and the first part of the duodenum, produce a kink at the junction of the first and second parts of the duodenum sufficient to obstruct the free passage of food.—The PRESIDENT believed that muscular wasting was really at the bottom of many forms of dilatation. The extent of the dilatation could be determined by giving the patient effervescent powder or by filling the stomach with large quantities of fluid.

Dr. E. MACDOWEL COSGRAVE read a paper on two cases of Relapse in Scarlet Fever. One was a girl, nine years of age, who was admitted into Cork-street Fever Hospital on Nov. 12th, 1896, suffering from a severe attack of scarlatina anginosa, the temperature falling to normal on the ninth day. On the twenty-eighth day, whilst desquamation was occurring in large flakes on the feet, the child had an attack of vomiting, the temperature ran up to 105·8° F., and a punctiform rash appeared, the tongue and pharynx being also typically affected, and albumin appearing in the urine. On the eighth day of the relapse secondary desquamation commenced and gradually spread over the body. The second case, also a girl aged nine years, was admitted to Cork-street Fever Hospital on Nov. 27th, 1896, suffering from well-marked scarlet fever. Eighteen days after admission, whilst free desquamation was going on, the child complained of headache and sore-throat, the temperature rose to 105·8° F., and a punctiform rash appeared; desquamation where occurring was increased, and where finished was repeated.—Dr. J. W. MOORE agreed that true relapses had occurred in Dr. Cosgrave's cases, and said that by means of isolation hospitals it was possible to produce many cases of relapse in scarlet fever, provided that the patients were kept in the wards long enough.

Dr. JOSEPH REDMOND read a paper on the Treatment of Cancer with Celandine (chelidonium majus). He exhibited patients suffering from epithelioma of the tongue and of the lip, and read notes of two cases—one of cancer of the œsophagus and the other of cancer of the liver. All the cases were improving under treatment with celandine.—The PRESIDENT said that it was remarkable that so little pain had been caused by the use of the drug, seeing that it was an irritant and an active narcotic poison.—Dr. J. W. MOORE said that some of the cases brought forward by Dr. Redmond were a little open to doubt as being cases of cancer, and that the symptoms were much more like acute dyspepsia.—Dr. REDMOND, in reply, said that he had never noticed any intense diarrhœa after administration of the drug.

MERTHYR TYDVIL HOSPITAL.—A meeting was held at Merthyr Tydvil on March 15th, under the presidency of the high constable, for the purpose of raising a fund in support of the endowment of the Diamond Jubilee Ward of the Merthyr Tydvil Hospital. The chairman announced that excellent progress had been made towards raising the sum of £7000, which it had been suggested would be sufficient to endow the five beds which the ward would accommodate.

Reviews and Notices of Books.

Royal Infirmary Clinique. By ALEXANDER JAMES, M.D., F.R.C.P. Edin., Physician to the Royal Infirmary, Edinburgh. Edinburgh: Oliver and Boyd. 1896. Pp. 166. Price 5*s.*

THIS small volume contains sixteen lectures delivered by Dr. James in the wards of the Royal Infirmary, Edinburgh. They are excellent reading and amply confirm the reputation of the author as a clinical teacher. A case of pulsating Tuberculous Empyema is well described, and the conditions leading to pulsation in pleural effusions are fully discussed. Two of the most interesting chapters are those on a case of Renal and Cardiac Disease, with special reference to the Diurnal and Nocturnal Excretion of Urine and a case of Primary Contracting Kidney. The latter lecture is so good as to be well worthy of comparison with Trousseau's work. Dr. James brings out very clearly the importance of regular testing of the relative amounts of day and night urine as a valuable indication of organic renal disease (p. 39): "In health the proportion of urine passed during the day hours is very much greater than that passed during the night. Roberts, for example, with a total daily quantity of 30 oz. 6 dr. of urine, gives for the sixteen hours of waking 30 oz. 2 dr., and for the eight hours of sleep only 4 dr. This gives as the amount of the secretion per hour for the day a little less than 2 oz., and for the night about ½ dr.; or, splitting the total quantity into two, one representing the amount passed between 8 A.M. and 8 P.M. and the other the amount passed between 8 P.M. and 8 A.M., this would give for the day quantity about 27 oz., and for the night about 3½ oz." He quotes Dr. Claude Wilson's observations: "That in debility, however produced, the diurnal and nocturnal rates approximate to each other, that this is specially marked in cases of cardiac disease, and more so still in organic disease of the kidney. One case is especially interesting, in which the approximation between the day and night rates of excretion was sufficient to make me strongly suspect organic (waxy) disease of the kidney, though there was no noticeable polyuria nor any albumin. This patient died two months later, when he was found to have extensive waxy disease of both kidneys as well as of other organs, though no albumin had been detected in his urine until a week before his death, and then only a trace." Dr. James sums up: "Of course alterations can occur in other morbid conditions and even occasionally in health, but when it occurs habitually and cannot be explained as due to other morbid causes it may enable you earlier than any other symptom to contemplate the onset of organic renal disease." The point is one which deserves much further precise investigation. In passing we would protest against the use of the word "cirrhotic" (p. 35) to describe the small granular kidney; it has become more customary to do so of late, but it is undesirable. The two cases of cirrhosis of the liver in children are of great interest clinically from the fact that Dr. James lays stress on the relationship which seems to exist between tuberculous infection and cirrhosis of the liver. Both in children and in adults the connexion appears often to be definitely more than a mere coincidence. The lectures on Friedreich's Ataxy and Addison's Disease are very good.

A Book for Every Woman. Part I.: The Management of Children in Health and out of Health; 1895. Part II.: Woman in Health and out of Health; 1897. By JANE H. WALKER, L.R.C.P. Irel., L.R.C.S. Edin., M.D. Brux., Physician to the New Hospital for Women, &c. London: Longmans, Green, and Co. 1897. Price 2*s.* 6*d.* each part.

THE first part of this book, as indicated in the title, is concerned with the management of children in health and out of health. In the introduction the author defines a healthy child as "one who is free from self-consciousness, whether in mind or body." The object of the volume is "to give plain and simple directions which, if carried out, will tend to keep healthy children well and help delicate children to become stronger." The author is strongly opposed to the practice of giving children any alcoholic beverages whatever. As she says, they are never necessary for a healthy child, and no doubt, besides being unnecessary, they may easily be mischievous. A diet table is given for children of various ages, which may be useful to the inexperienced matron and others. In the second part of the work, devoted more especially to the adult woman, there is a great deal of good advice of a necessarily more or less general character. As regards cycling, we observe that, according to the author, "it exercises the legs and lower part of the body and increases lung power. Like everything else, it is best done by one in good muscular training, and a girl, who perhaps has never done any other active thing, who compresses her ribs with stays and her feet with shoes, such being the fashion, who buys a bicycle and learns to sit it, such also being the fashion, is very likely to 'override' herself and find that it does not agree with her." No doubt, as the author says, "the extraordinary benefit derived from it by so many young women proves only how little exercise they were in the habit of taking. A daily gentle run of a couple of miles would be much cheaper and far better training. Cycling is useful and it is delightful and it is fashionable, but it is not magical." She has also something to say about most other forms of muscular exercise, from gardening to billiards. There are several useful dietaries, such as a diet for fat people, a diet for thin people, and a diet for gouty and rheumatic people, which may be of use to those who like to get the advice they require out of books. We should say that the two volumes will probably prove useful to those for whom they are intended.

LIBRARY TABLE.

Transactions of the American Dermatological Association at its Twentieth Meeting, in 1896.—The meeting last year was at Hotsprings, Virginia, under the presidency of Dr. A. R. Robinson of New York. The Transactions are reprinted from the November and December numbers of the *Journal of Cutaneous and Genito-Urinary Diseases*, but without the plates or cuts. The report is much shorter than usual or else there was less work done. We miss the list of members, with their addresses, which was very useful for foreign workers in dermatology. Among the most interesting papers was A Case of Symmetrical Morphœa attended with the Formation of Bullæ and Extensive Ulceration by Dr. Morrow, and A Milium-like Condition of the Lips by Dr. Fordyce, of which there is a coloured illustration in the November number of the journal already mentioned. A Favus-like Eruption of the Oral Mucous Membrane is published by Dr. Winfield. Dr. Bowen's two cases of Mycosis Fungoides and Sarcomatosis gave rise to an interesting discussion, as did also Dr. White's paper on the Effect of Diet and Alcohol upon the Causation and Course of the Eczematous Affections and Psoriasis. A Pathological and Clinical Classification of the Diseases of the Skin by Dr. Duhring did not elicit much approval from his auditors. Some Glycosuric Dermatoses by Dr. C. W. Allen and Xanthoma Diabeticorum by Dr. Robinson excited interest. This case does not appear to be a typical one. There had never been any glycosuria or jaundice, although the patient had suffered from gall-stones. A large proportion of the lesions had disappeared for a time, but had recurred. The lesions were the size of a pin's point to that of a pin's head, yellowish, with a tinge of red. The urine contained 20 per cent. by

Hosted by Google

bulk of albumin, but no sugar. Impetigo Contagiosa Universalis was the title of a paper by Dr. C. W. Allen. Some doubt was thrown upon the diagnosis by some of the speakers, and as staphylococcus aureus had not been searched for the true nature could not be proved. Dr. White of Boston was elected president for the ensuing year.

Cerebral Herniæ (Cephaloceles) and their Treatment. By Dr. N. K. LUISENKOF. Moscow: The Yakovlef Press. 1896. Price 2½ roubles.—This excellent monograph of 232 pages is a valuable contribution to the literature of the subject with which it deals. It presents an exhaustive discussion of the various forms of this not very uncommon lesion both from their anatomical and clinical aspects. The author is of opinion that the large majority of so-called congenital cerebral herniæ are not true herniæ or protrusions of brain substance, but are teratoid formations, resulting from imperfect separation of the neural canal in the process of development, and sometimes containing no nerve substance at all. All forms of hernia, encephalocele, hydrencephalocele, and meningocele are but different degrees of the same embryonic lesion. They should be treated as other new formations by complete excision of the tumour and, if possible, closure of the opening in the skull by an osteoplastic operation. Only large exencephala, or true herniæ of the brain with much protrusion of brain substance and great deficiency of the skull, are unsuitable for operation. If a fatal result follows the operation it is almost invariably the result of some complication, more particularly of a septic character, and not of the operation itself. The monograph, which was presented by Dr. Luisenkof as the thesis for his doctor's degree, is illustrated with plates showing the aspect of patients suffering from cephalocele, both before and after treatment, and the macroscopic and microscopic appearances of the bones of the skull in typical cases.

Premature Burial, and how it may be Prevented. By WILLIAM TEBB, F.R.G.S., and Colonel EDWARD PERRY VOLLUM, M.D., late Medical Inspector, U.S. Army; Corresponding Member of the New York Academy of Sciences. London: Swan Sonnenschein and Co. 1896. Pp. 400.—It is seldom our ill fortune to come across such a compilation as this volume. That states of trance may resemble death is a commonplace known to every medical man of any experience. In this country at any rate, where a comparatively long period elapses between certification of death and burial, there is no real danger of practical confusion between the two. The tests are ample, and if a shadow of a doubt exists a short delay till putrefaction definitely sets in can in the future be insisted on, as it so often has been in the past; and yet the authors have had the temerity to produce this book, which must needlessly excite the fears of any unfortunate individual who is unlucky enough to read it. Newspaper cuttings, second-hand information, and unverified statements form the chief basis on which the writers build.

The Nurses' Dictionary of Medical Terms and Nursing Treatment. Compiled by HONNOR MORTEN. Third and Revised Edition. London: The Scientific Press.—This manual may have been revised, but if so it has been very carelessly done. For instance, ægobronchophony is defined as "a bleating sound heard on auscultation—a symptom of pleuro-pneumonia." Collodion is said to be gun-cotton dissolved in alcohol. In the preface we are told that "ectomy" means cutting. The purely nursing directions in the book, however, are apparently correct. We might remark that Epsom salts are not the "sulphite" of magnesia.

The Horse: His Life, His Usage, and His End. By Colonel W. LISLE B. COULSON. London: William Reeves. 1896. Price 2*d.*—An earnest and well-written plea for the better treatment of horses. The remarks about the use of pearing-reins, or rather their abuse, are worthy of everyone's attention.

An Autumn Singer. By GEORGE M. GOULD, M.D. Philadelphia: J. P. Lippincott Co. 1897.—This is a small collection of poems, sonnets, and *vers de société*. The sonnet entitled "Unrest" is to our mind the best.

Current from the Main. By W. S. HEDLEY, M.D. Edin. London: H. K. Lewis. 1896. Price 2*s.* 6*d.*—This publication is mainly a reprint of articles which have already appeared in our columns in 1892, 1895, and 1896. Electricity is so much used now as a therapeutic agent, the current being in many instances supplied from the main, that Dr. Hedley's cautions as to the dangers of leakage currents in an electric bath will be found of great value.

Elementary Bandaging and Surgical Dressing. By WALTER PYE. Revised and partly Re-written by G. BELLINGHAM SMITH. Seventh Edition. Bristol: John Wright and Co. London: Kegan Paul and Co. 1896. Price 2*s.*—This little book is mainly a re-issue of portions of the late Mr. Pye's "Surgical Handicraft." The portions on the dressing of wounds have been brought up to date by Mr. Bellingham Smith, and the book will be found very useful for dressers and, up to a certain point, for travellers in wild countries.

A Collection of Ballads. Edited by ANDREW LANG. London: Chapman and Hall. 1897. Price 2*s.*—The old ballad is not only to be valued for its subject, or in many instances its music and pathos, but also for being a mine of old beliefs. The idea of paying tithes to the devil is illustrated in the present collection by the ballad of Tamlane. We might remark that the late Sir James Simpson's grandfather buried a cow alive as a sacrifice to the devil, and also reserved a corner of his farm, albeit the most unproductive portion, for the exclusive use of the same personage.

Physical Exercises in Gymnastics for Girls and Women. By F. J. HARVEY. London: Longmans, Green, and Co. 1896. Price 3*s.* 6*d.*—This is a well thought out little book for the use of teachers in high schools, &c., giving simple and clear directions for organised physical exercises. It is copiously illustrated with photographic plates, and the little essay on the necessity of physical training and exercise contains plenty of common sense.

What to Do in Cases of Poisoning. By WILLIAM MURRELL, M.D. Brux., F.R.C.P. Lond. Eighth Edition. London: H. K. Lewis. 1897.—This well-known and useful little book has been revised and brought up to date by the addition of much new information, and also what the book greatly lacked before—an index. It is an excellent work for the country practitioner, who is often far removed from the help of his professional colleagues.

Our Weights and Measures. By H. J. CHANEY. London: Eyre and Spottiswoode. 1897. Price 7*s.* 6*d.*—Nothing could be more perplexing than our present system—if we may call it a system—of weights and measures, and this is largely to be attributed to the peculiar origin of our standards. Uniformity is hardly to be expected when we remember that the original weight of an English penny called the "sterling" was defined to be that of "thirty-two grains of wheat, well dried, and gathered out of the middle of the ear"; or that "three barleycorns laid end to end" was to be regarded as an inch," subsequently modified by providing that the barleycorns should be "round and dry." The work before us is a practical treatise on the standard weights and measures in use in the British Empire, and the writer is the superintendent of the Board of Trade Standards Department, so that every reliance may be placed upon the information and data it contains. The history of the evolution of our systems of weights and measures from almost prehistoric times is exceedingly interesting, while the account of the present standards and methods of standardisation will be

Hosted by Google

very valuable to many, and the work is made more instructive by the fact that the standard instruments described are admirably illustrated. It is an indispensable book of reference to scientific men as well as to those engaged in commercial life.

Medical Report of the Royal Infirmary, Liverpool.—This report, the first one issued, contains medical, surgical, and pathological statistics drawn up by the registrars of these subjects respectively—namely, Dr. E. A. Smith, Dr. H. T. Nixon, and Dr. R. Boyce. They are apparently very full and carefully done, but we should suggest in subsequent volumes the addition of a table of all operations performed (and not only gynæcological ones) and some figures as to the administration of anæsthetics; moreover, we do not think that the names of patients should be given in full. The notes upon post-mortem examinations should prove of great value. One case is specially interesting—that of a girl, aged fourteen years, who had died from cirrhosis of the liver. There is a misprint in this table, p. 86, the column which should be headed "age" being headed "No."

The Law of Wills ("Wilson's Legal Handy Books" Series), by C. E. STEWART, M.A., Barrister-at-law, and published by Mr. Effingham Wilson of the Royal Exchange, price 1*s.* 6*d.*, has reached another edition, to which has been added a new chapter dealing with the Finance Act of 1894 so far as it affects the rate of the death duties. Mr. Wilson's series of legal handy books are well known and have deservedly become popular.

JOURNALS AND REVIEWS.

The Phonographic Record.—Mr. Lamming Burton, in the March issue, gives much information for those about to "take a ship." Though the ship may be small it matters not if the captain be a sailor and a gentleman; and before accepting a ship it is well, if possible, to see "the old man." The next thing is to see the cabin and overhaul the medical stores a few days before sailing. Shelves are to be preferred to medicine chests; and, whatever else is carried, chloroform, solution of cocaine, hypodermic outfit, and surgical dressing-case are essential. Refreshing his memory in the pages of a good materia medica, the ship surgeon writes out his order for the drugs to be sent on board without delay. All drugs and instruments in stock are to be examined and held guiltless of activity until they are found to possess it. Ammonia may be scentless, chloral hydrate gone to liquid, pills mouldy or their freshness external, and "the heat of a voyage down South has fused the set of catheters into one solid mass." Bandages and no splints will not do much good, and new enema syringes, fresh catheters, and a couple of trusses should be taken. On the voyage the surgeon's position may be made or marred by his mode of dealing with his first patient. The first case may be a genuine one, but, adds Mr. Burton, "be sure of it." Firemen most often need the medical officer, and we are told their work is "the hardest and worst to be found below heaven"; but a drunken spree before sailing has often to answer for the fireman's illness, and the men are ever ready to be off work and malinger. Mr. Burton says that among the crew of a steamship cases of constipation, diarrhœa, gonorrhœa, cramps, pediculi, debility, syphilis, cuts, burns, hernia, and fractures are commonest, and their frequency in the order given. In noting that the surgeon must remember and be prepared to treat the diseases of the country to which he is bound, Mr. Burton says that ague, dysentery, black-water fever, and malarial boils will be encountered in Equatorial Africa, yellow fever in South America, cholera in India, and sunstroke in all hot countries.

In the *Veterinarian* for March E. W. Carlier's paper on the Pancreas of the Hedgehog during Hibernation is concluded. Dr. Carlier notes that during secretion the cells become smaller, and the lumen of the acinus larger, the nucleus becomes enlarged and clear, and the chromatin is more widely distributed. The ducts have the usual structure. He can find no muscular sheath around the larger ducts, whose walls, however, are surrounded by connective tissue and are pierced by mucous glands. The central acinal cells, which have been described by some as epithelial in character and by others as multipolar nerve cells, are not numerous, but can usually be seen near the mouths of the acini. The amount of connective tissue in the pancreas of the hedgehog is very small; the lymphatics are numerous, as are also the ganglion cells situated in the fibrous tissues surrounding the larger vessels. The Pacinian corpuscles described by Harris are fairly numerous in the hedgehog near the head of the pancreas, as are also the islands of Langerhans; these latter are small, and contain many large cells filled with fine eosinophilous granules. Veterinary-Major F. Smith concludes his observations on the Symptoms and Lesions of Anthrax in the Horse, in which he gives a very full account of the post-mortem appearances of the thoracic and abdominal organs in this disease. He points out that although the whole of the symptoms are found in very few cases, and that it is quite likely that only the bowels and spleen may be affected, or the throat and lungs, or only the throat, and so on, that the lesions described are so typical of equine anthrax in India that there is no other disease of the horse for which they could be mistaken. A note on Filaria Oculi of the Horse by Professor Neumann of Toulouse, and Notes on the Presence of Ganglia in the Lung by A. E. Mettam, and on the Terminal Portions of the Abdominal Aorta and Immediate Collateral Branches by H. V. Mossmann are followed by a series of Clinical Cases by E. Wallis Hoare, by Archibald Hodder, by the Editor, and by W. Murgatroyd; and accounts of the month's progress and reports of the meetings of societies.

In the March number of the *Veterinary Journal and Annals of Comparative Pathology* "Borth" continues his Essay on Diseases of Animals Transmissible to Man, completing his remarks on the tape worms and round worms, and taking up the specific infective diseases, mentioning anthrax, diphtheria, and tetanus. These accounts are somewhat sketchy, but they contain the ordinary information. The Principal of Bombay Veterinary College, Veterinary-Major J. B. Mills, gives a short account of a Mysterious Disease among Horses in Mombasa, Africa. This disease appears to be some form of the Nagana disease, which is supposed to be spread by the tsetse fly, on which Surgeon-Major Bruce is at present making a series of investigations. In this number there are some excellent photographs given to illustrate sprain of the suspensory ligament and flexor tendons in over-reaching in the horse. This application of photography should be of very great value. A good case of recovery of a horse from tetanus after the injection of antitetanin is described, and it appears that the value of antitetanin is greater in connexion with the treatment of tetanus in the horse than it is likely to be in the human subject. In an editorial article dealing with the new Public Health Bill for Scotland the editor complains of the attempt that is being made to give the medical officer of health the power to deal with animals and animal diseases which he maintains should certainly be in the hands of well qualified veterinary surgeons. Reports and proceedings of societies, an account of an experimental study of the aspergillus fumigatus, and an account of the regulations for admission to the Army Veterinary Department, 1897, with an abstract of a paper on the Relationship of the Liver to Fats by D. Noel Paton, legal news, abstracts from foreign journals, and notes and news and reviews make up a very readable number.

Hosted by Google

Liétopis Russkoi Chirurgii (*Chronicle of Russian Surgery*). Thirteenth year. Part II.—The present number of this excellent Russian journal opens with an illustrated article by Dr. Serapin on the Treatment of Goitre by various thyroid preparations. Of thirty cases under the writer's own observation two were "completely cured"; in nine the result was "good," only a trace of enlargement being left; in ten the success was "moderate"; and in nine the result was negative or the improvement was very slight. Success was therefore met with in 70 per cent. of the cases. Dr. Sapiejko records six cases of the Operative Treatment of Lupus. He is averse to any attempt to treat the disease by medication or by palliative surgical measures. Radical excision, removing the whole affected skin and subcutaneous tissue and not less than one centimetre of the healthy skin around, is advocated as the only measure offering the hope of cure. Subsequent plastic operations are, of course, necessary. A rare case of Supernumerary Nipple is described by Dr. Kumberg. The patient was a male Uzbek Tartar, and the extra nipple was in an unusual position, lying over the eleventh dorsal vertebra and almost in the middle line. Two successful osteoplastic operations for the radical cure of Spina Bifida are recorded respectively by Dr. Gorski of Odessa and Dr. Orlovski. The first patient was aged one year and eight months, and the second only five months; in both cases the treatment was completely successful. Among the reports of Russian surgical societies will be found a discussion on Professor Ratimof's case of Actinomycosis of the Cæcum; more than one of those who took part in the discussion had seen similar cases, and had found large doses of iodide of potassium the most satisfactory form of treatment.

The Middlesex Hospital Journal, No. 2, Vol. I.—The issue of this journal for March only strengthens the favourable impressions conveyed by the first number. A short description of the Davy-Faraday Laboratory is well illustrated, and there is some interesting clinical matter. An article on "The Synthesis of Proteid Matter" is commenced by Mr. C. Reissmann, F.C.S.

St. Thomas's Hospital Gazette for March opens with a portrait and obituary notice of the late Sir Thomas Spencer Wells, "this great and epoch-making surgeon, whom St. Thomas's Hospital is proud to claim as one of her oldest and most distinguished students." Mr. W. G. Sutcliffe continues his recollections of the second Matabele war. Under the heading "A New Remedy" is published the following letter. Possibly it is as well to point out that the "very tall built gentleman" is the present President of the Royal College of Surgeons of England.

St. Mary's Hospital Gazette publishes a list of sixteen cases of death under chloroform administration which have occurred since the commencement of this year. "This high mortality," it says, "must in large part be due to careless administration of the anæsthetic, either sudden overdose, or from inattention to the respiration, rather than to any unavoidable toxic effect of the drug. Since the list was compiled four more deaths under chloroform have been reported, making twenty cases in England alone in two and a half months."

Analytical Records
FROM
THE LANCET LABORATORY.

AUSTRIAN PINE PRODUCTS (JOSEPH MACK).

(THE REICHENHALL SYNDICATE, LIMITED, 60, QUEEN VICTORIA-STREET, E.C.)

THE basis of all these good preparations is the essence obtained by distillation from the *pinus pumilio*, which is found in the highest regions of the Austro-Bavarian Alps, the tree selected for the special purpose occurring at an altitude of not less than 6000 feet above the level of the sea. The essence is a fragrant, clear, mobile, and colourless oil, which we find has a constant boiling-point of 78·5° C. It is therefore readily volatilised. Probably the beneficial action which it undoubtedly has when employed as an inhalant, and also when taken internally, is due to its inherent antiseptic properties, and also to the fact that it readily develops peroxide of hydrogen on contact with moisture. A simple experiment illustrates this. On shaking the oil with water the liquid will be found to contain peroxide of hydrogen by the usual tests. It may thus serve as an oxygenator and purifier of air. The Austrian pine products include the following preparations: Pectoral Syrup, for use in pulmonary disorders; Pectoral Paste, used for a similar purpose as a lozenge; Capsules of Pine Essence for administration in bronchitic and allied affections; Bouquet des Alpes, a refreshing and fragrant application for the handkerchief; Anti-rheumatic Bath, a more or less crude preparation containing the entire pine principles, and evolving when placed in hot water an agreeably aromatic smell; Sanitary and Toilet Soap, a soap, as our tests proved, of excellent quality. Not the least favourable feature of these preparations is the fact that while beneficial in certain lines of treatment they are very agreeable to use, the basis being characterised by an especial fragrance.

HAY'S FOODS.

(WILLIAM HAY, GROSVENOR-STREET, HULL.)

An examination, both chemical and microscopic, indicates at once that these preparations possess a high degree of nutritive power and digestibility. The infants' food, for example, contains the constituents of wheat flour of a superior quality, carefully modified by cooking so as to present no obstacle to assimilation, while it contains about 15 per cent. of germ with 15 per cent. of active malt. It possesses a pleasant, distinctly sweet, and malty flavour, and, as might be expected, is very soluble. The appearance under the microscope confirms this statement in regard to its composition, as well as in regard to its method of preparation, which enhances the nutritive value of the constituents. It follows that the proportion of proteids is admirable, while the yield of indispensable mineral nutrients is found to be satisfactory. In a word, the food contains a maximum proportion of all the elements necessary for the sustenance and growth of the infant. "Frumentine" is a pleasant wheaten food, containing a satisfactory proportion of wheat germ. From the character of the preparation made from it in the form, for example, of porridge, the cereal selected is clearly of a superior kind, the flavour being

Hosted by Google

pronouncedly wheaten and acceptable. It affords, therefore, not only a highly nutritious but a palatable food.

NEW PALATINOIDS.
(OPPENHEIMER, SON, AND CO., 14, WORSHIP-STREET, E.C.)

The palatinoid, consisting of a gelatin case in shape like two tiny watch-glasses cemented edge to edge, is well adapted for the administration of creasote and guaiacol. The nauseous character of both drugs is thus avoided in the mouth. The creasote employed in the present instance is said to be specially pure, and therefore non-corrosive and free from any bleaching effects upon the mucous membrane. We have also recently received palatinoids containing a definite quantity of amyl nitrite. They possess the advantage that they may be crushed within the folds of a handkerchief and administered in that way as an inhalation without any of the risk which arises from crushing containers made of glass.

(1) WHOLE MEAL BREAD AND (2) SELF-RAISING FLOUR.
(E. MOGG, ST. MARY-STREET, BRIDGWATER.)

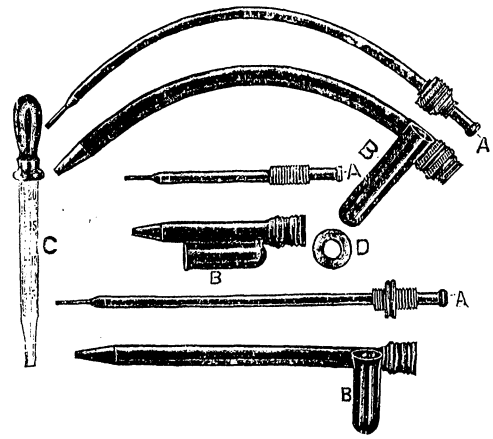
The specimen of whole meal bread was characterised by the entire absence of irritating particles of bran, although the proportion of mineral matters, phosphates, &c., which occur abundantly in bran was high. The bread was evidently malted, and possessed a good wheaten as well as malty flavour. Despite the rich proportion of soluble carbo-hydrates resulting from the introduction of malt, the loaf presented a good light and spongy texture. The self-raising flour acts well, as we found on preparing a specimen of bread in the way directed. The resulting loaf is free from objectionable saline taste, which is always apparent when ordinary baking powder has been used. Judging from the excellent taste and texture of the resulting loaf the flour selected is evidently of superior quality.

"AMBROSIA."
(EVANS, GADD, AND CO., FORE-STREET, EXETER.)

The formula of this preparation, which is a combination of Devonshire cream with an active extract of malt, is an excellent notion. Under the microscope it is not possible to distinguish particles of fat in a separate condition, but on adding water myriads of oily globules are seen to dissociate. The preparation should afford a valuable substitute for cod-liver oil, especially as the fat of cream, as is well known, is more easily assimilated than many other fats, while the co-existence of an active malt essence is calculated to make appropriation still more secure. Moreover, the flavour is attractive. We are not certain that this preparation will keep well.

CALLARD'S NON-FARINACEOUS INFANTS' FOOD.
(CALLARD AND CO., 65, REGENT-STREET, W.)

The microscope showed the complete absence of insoluble starchy matters in this food. It contains rather the digestion products of starch—namely, dextrine and sugar. The preparation is therefore almost completely soluble in excess of cold water. It possesses a sweet and marked dextrine like taste. The soluble carbo-hydrates are judiciously balanced by an excellent proportion—amounting to nearly a seventh part—of proteids. Nor is it destitute of those mineral constituents which are none the less important factors in the infant's diet. The food is evidently prepared with a correct knowledge of the special requirements indicated.

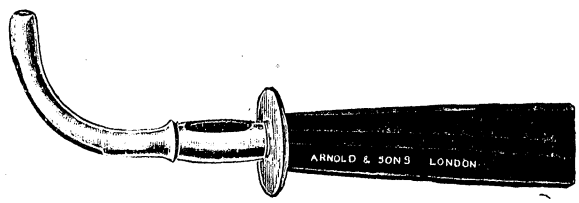


KYDDE'S FOOD.
(KYDDE AND CO., 10, SOUTHWARK-BRIDGE-ROAD, S.E.)

This is a food prepared in accordance with the requirements of infants and invalids when used with milk as a necessary adjunct. It is a white powder containing wheat starch, and is sweet and malty to the taste. It is made digestible by having been malted, the presence of a good proportion of soluble carbo-hydrates being due to this method. When prepared in the way prescribed it is both nutritious and palatable.

New Inventions.

A CELLULOID SPRAY PRODUCER.



MR. THOMAS WOODRUFF, of 43, Cavendish-road, Withington, Manchester, has brought out a new spray producer, specially adapted for the accurate administration of medicated solutions or liquids in minute quantities. It is made in three forms so as to allow of the direct action of the spray on the larynx, pharynx, or nasal cavity. In the engraving B represents the outer tube, about three-eighths of an inch in external diameter, with a short wide tube to hold the solution attached at the end furthest from the tapering nozzle. A is the air-tube which passes inside the other one, and is fixed in its place by means of a screw thread cut in the wide portion and also by the lock-nut D. Each pair of tubes, as well as the lock-nut, is made of transparent celluloid. C is a graduated glass pipette with a compressible

indiarubber cap for taking up measured quantities of solution. Air is driven into the tube A by an indiarubber bellows ball worked by hand in the ordinary manner. The lengths of the two straight outer tubes are five and a half inches and three inches respectively. The instrument produces a copious jet of fine spray, well adapted for the purpose for which it is designed. It can be readily taken to pieces for the purpose of being cleansed. Each of the three forms may be obtained separately.

TRACHEOTOMY PILOT.

THE accompanying illustration represents a modification of the usual tracheotomy pilot which I have devised, and which is designed to do away with the dyspnœa and struggling that are so often seen when the inner tube is being inserted after being cleansed. It consists of a hollow silver tube with

an aperture allowing the free entrance of air at its upper end. The tube is fixed into the handle by a screw, this enables the metal portion of the instrument to be thoroughly cleansed; the handle is provided with a shoulder, which assists in keeping the fingers of the operator away from the aperture at the upper end of the tube without interfering with the outer tube. Messrs. Arnold and Sons, London, are the makers.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1897.

THE public meeting for promoting a national memorial to EDWARD JENNER, held in the theatre of the University of London on Wednesday, March 31st, was an event of great importance. Lord LISTER, who is at the head of the movement, hopes for such success as will place the name of JENNER in this country on the same footing as that of PASTEUR in France, and to raise such a sum as will enable the authorities of the British Institute of Preventive Medicine, henceforth to be associated with the name of JENNER, to pay their devoted and brilliant servants somewhat more adequately than they do at present. The chief interest of the movement is in the attempt to link the names of JENNER and PASTEUR and the other members of the great army of research whose work has sensibly reduced the terror with which we regard such diseases as diphtheria, tetanus, anthrax, and even plague. The justice of this association was fully recognised, not only by such men of science as Lord LISTER and Professor MICHAEL FOSTER, but by representative laymen like the Duke of WESTMINSTER, Lord HERSCHELL, Lord DAVEY, and Sir ALFRED LYALL. As Professor MICHAEL FOSTER said, the doctrine of attenuation was started by JENNER, and those who have developed it so splendidly in recent years have been foremost in their admission of the fact. No monument to JENNER could take a form more honourable to him than one which connects him with workers who lived a hundred years later in point of time, and whose work gives lustre to the end of this century and promises still greater results in the next. We most heartily wish the greatest success to this movement. It will be a national discredit hereafter if the noisiness of a group of faddists is allowed to overpower the still small voice of science and of common sense in such matters. What is the use of a nation claiming a JENNER and a LISTER if their work is to be constantly disparaged? Other nations will not be slow to benefit by our stupidity and to do that honour to our great men which is denied to them in their own country.

Whether the hopes of Lord LISTER and his colleagues are realised or not the importance of the meeting of Wednesday remains. The speech of Lord HERSCHELL, who spoke as President of the Royal Commission on Vaccination, must set for ever at rest the question of the efficacy of public vaccination. His was emphatically the speech of the occasion, and was delivered with so much clearness of language and so much force of conviction as to leave all gainsayers without any possible credit. He explained with what entire want of prejudice he went into the inquiry, with the determination to accept whatever results the evidence yielded. In the end, to use his own language, he "was surprised at the force of the evidence in favour of vaccination." The force of this evidence has been felt by medical men for generations, during which time they have ministered with practically absolute immunity in successive epidemics of small-pox. But it is something new to have it expressed so forcibly by an ex-Lord Chancellor, who, as Professor MICHAEL FOSTER said, has heard more of the evidence against vaccination than any living man, and who is exceptionally capable of weighing the value of it. Lord HERSCHELL gave a few illustrations of the sort of evidence that had so surprised him, showing the consistent and uniform relation between the prevalence of effective vaccination in a community and its protection from small-pox and the unerring punishment of those communities that neglect it. There was evidently only one thing that impressed him as much as the evidence in favour of vaccination, and that was the mental condition of those who resist it. It was a veritable wonder to him, hardly to be explained even by the hardening effect of prejudice on a certain class of minds.

Lord HERSCHELL not only lifted vaccination above all question and quarrel, but he defended the methods of JENNER as scientific above the measure of his time, in which view he was supported by both Lord LISTER and Professor MICHAEL FOSTER. One of the most effective parts of Lord LISTER'S speech was his tribute to workers like M. HAFFKINE in plague-stricken communities, who, at the risk of their lives, are developing antitoxins which are found to confer a measure of security upon those exposed or already affected. After such an exposition of the achievements of JENNER and his successors it is high time for their detractors to be silent, and for statesmen, municipal and Imperial, to ignore such detraction; and it is for the public to do high honour to the heroes who wage battle with an enemy more terrible and more destructive than war.

THE interesting account which we published last week as to the sanitary conditions under which the city of Bombay has now acquired a reputation for plague, in addition to that which has so long attached to it in so far as cholera is concerned, raises certain questions which are of very grave importance. In England we can at least claim that, even if infectious disease in our midst should constitute a danger to other countries as well as to ourselves, we have during a considerable number of years done our best towards the removal from the midst of our populations of those conditions which are now universally recognised as tending to the increase and spread of dangerous infectious disorders. As regards British India, we have often been told that, scattered as so much of the population is in villages over an immense area, there are difficulties to contend with which we in this country cannot appreciate. We have also been told that the tank system of water-supply and the conditions surrounding the native hut were of a sort that made reform almost impossible, and that questions of religious observances also stood in the way of the changes that were needed in the interests of public health. But we must confess that we were not prepared to learn the extent of utter neglect of the elements of sanitary

Hosted by Google

administration which prevails in some of the great cities of British India, even if the remark does not apply to all. The story of the conditions under which plague has made its home—for a time at least—in Bombay comes to us from two sources, both trustworthy, and both resembling each other in the dark picture which they draw. We have already referred to the special article from a correspondent in Bombay. He tells us that in this great centre of commerce and business many of the streets are very narrow and crooked; that in these quarters the houses have been built six storeys high; that the density of population per acre reaches a figure unequalled anywhere in the world; that overcrowding abounds, and that no active measures have been taken to prevent it; that even domestic servants rarely receive any training in sanitary habits from their employers; that well-nigh every sanitary precaution is neglected; that at night the people throw every form of filth into the narrow streets; and that, in short, a large portion of the population constitutes, by reason of habits which are not only tolerated but apparently assented to by those in authority, a constant and standing element of danger.

The confirmation of this accusation against those in authority in the city comes from the highest possible source. As is well known, our correspondent who was in Venice during the sittings of the International Sanitary Conference sent us from time to time an account of its proceedings. One point was, however, not referred to—namely, the statement made by Surgeon-Major-General CLEGHORN to the delegates assembled there on his arrival from India. We shall have opportunities hereafter of reverting to much in that statement of which we may feel proud as to the preventive action taken when it was clearly seen that no half-measures were of any use. But for the moment we would recall the fact that when the Director-General of the Indian Medical Department gave a description of those parts of the city of Bombay in which plague was then and still is epidemic his statement fairly astounded a number of delegates, who were under the mistaken impression that under British rule there was always sanitary progress. Our correspondent was informed that a special debate on this statement as to Bombay would take place, and hence we awaited the debate before entering into the subject. For some reason or other the debate did not take place, or, if it did, no intimation as to it was allowed to leave the precincts of the Venetian Royal Palace. But we feel bound now to state that Surgeon-Major-General CLEGHORN'S description of the conditions of life in the native quarter of Bombay surpassed anything which our correspondent has embodied in his report; indeed, anything more appalling than the story of vast aggregations of human life in six- and seven-storeyed buildings run up in narrow streets, made foul with ordure and every conceivable filth, is only to be surpassed by the description given of the interior of these vast dwellings, where narrow passages, into which filth is also cast, are apparently at times lined on either side with living rooms without so much as a window. Indeed, as some delegates remarked when the facts were first announced, it would seem as if Bombay had done its best to secure for cholera a permanent tenancy, and also to prepare the way for plague or any other filth disease that it could manage to attract.

The circumstance, too, which causes most astonishment is that we are not here dealing with huts erected by natives or by a bygone generation, but with the arrangements inaugurated by a system of modern "civilisation," if we may so far prostitute the word, in connexion with a modern system of factories and cotton mills, the labourers in which have been housed in these dreadful rookeries. "The city," writes our correspondent, "was built before the existence of municipal influences." We do not understand how far this mends matters, for we have heard complaint that the grant of local self-government under municipalities was a great mistake in India. Whether this be so or not, the subject is one which it is not our province to discuss; but it is certain that some modern authority was responsible for allowing the present state of affairs to grow up in the native quarters of Bombay, and that some existing authority is responsible for allowing things to remain in the condition in which they now are. Our object is to urge that the responsible authority—be it central, provincial, or municipal—should not be any longer allowed either to permit streets to be laid out and tenement houses to be built as they have been in Bombay, or to allow conditions to remain which are a standing menace, not only to the city of Bombay, but to British India, and, through her ports, to the civilised world, and especially to Europe. Plague tends to die out in summer and to recrudesce in the following winter. If Bombay wants to prevent its recrudescence within the municipal boundary next winter, much more will have to be done than merely to control the disease in its existing haunts; those localities which time and neglect have allowed to grow up in such a way as to form a soil favourable to the disease will have to be dealt with in an energetic manner both in Bombay and elsewhere in India.

IN view of the steady increase in the number of insane persons coming under official cognisance, and the consequent feeling of alarm arising in the public mind, the Commissioners in Lunacy have deemed it judicious to issue a special report dealing with the subject. In 1859 the number of lunatics, idiots, and persons of unsound mind in England and Wales reported to the Lunacy Department was 36,762; in 1896 the number had risen to 94,446, showing a ratio to every 10,000 of the population of 31·38, as compared with 18·67 at the previous period. Both from a fiscal and social point of view these figures cannot but excite a feeling of apprehension, and the question naturally arises, To what is this enormous increase to be attributed? Is it due to a mere multiplication of numbers, or is it owing to a true increase of the disease itself? There is a prevalent idea, which has found frequent expression, that the apparent growth of mental instability in our midst is more or less connected with the conditions of modern life, its hurry and restless movement, its keen competition and struggle, its excitement and strain; and the Commissioners in the pursuit of their inquiries felt impelled to keep this argument steadily in view, although they state that previous

Hosted by Google

similar investigations did not afford confirmatory evidence on the point.

In order to make their inquiry as comprehensive as possible the Commissioners at the outset addressed a circular letter to the superintendents of all the county and borough asylums of England and Wales, asking their views in regard to the alleged increase of insanity, and requesting those of them who were of opinion that such an increase had taken place to specify the facts and figures on which their opinion was based and the apparent causes of the tendency. Of sixty-two superintendents and others from whom replies were received, ten were of opinion that occurring insanity had increased to a greater or less degree (one superintendent attributes the increase in his district during recent years largely to the after effects of influenza, and it is important to note that in the last report of the Edinburgh Asylum Dr. CLOUSTON laid much stress on this disease as a factor in the production of mental illness). On the other hand, thirty superintendents stated that there was no increase, whilst twenty-two were unable to arrive at any definite conclusion upon the subject. In some instances no very clear distinction was drawn between the increase of insane persons, as to which there can be no dispute, and an actual increase of insanity disproportionate to that of the population, respecting which there is a wide difference of opinion. The Commissioners have, however, drawn their own deductions from the information supplied to them and at their command. The statistical tables appended to the report clearly demonstrate that the increase of insanity has been almost wholly confined to the pauper class, the ratio having risen from 15·95 in 1859 to 28·44 in 1896 per 10,000 of the population. The ratio of private patients during the same period has only risen from 2·38 to 2·69. From this latter fact the Commissioners assume that the insanity-producing causes already referred to are not so potent as is generally supposed, because the private patients, upon whom those causes would have been most likely to operate severely, have scarcely suffered in any degree. It is open to doubt whether this conclusion is entirely justified, for it must be remembered that the assumption is based solely on the official figures, and no cognisance is taken of the reserve of this class of cases, which must necessarily be large, and is probably not so likely to be absorbed as the pauper class. The statistics indicate that the ratio of pauper lunatics to the total population is steadily increasing; but this method of calculation is not altogether reliable, for it has been shown by the Commissioners themselves, in their last annual report, that the ratio of pauper insane to the total pauper opulation has remained almost stationary during the last five years. The ratio of pauper insane to paupers of all classes gives the fairest estimate of the fluctuations of insanity in the country, and the latest returns show that the increase has been but slight during recent years. There can be no doubt that the increase of the pauper population in lunatic asylums has been due to causes foreign to an actual increase of the disease itself. The working classes are showing an enhanced appreciation of the benefits to be derived from the treatment of nervous ailments in these establishments, and they are more ready than formerly to send their relatives who have broken down from old age or other causes. The reports of the various superintendents are almost unanimous on this point.

The four-shilling grant now made towards the maintenance of pauper lunatics in asylums, and its loss on their removal to the workhouse, has no doubt largely influenced the action of boards of guardians; consequently there has been a steady diminution in the ratio of lunatics in workhouses or resident with relatives or others. Other causes at work are the re-distribution of cases already registered, but not yet classed as cases of first or occurring insanity, and the influx of cases that follows the provision of extended asylum accommodation everywhere. There is in the community a reserve of cases of insanity from which may be drawn a constant supply of new cases to be registered as suffering from first attacks on admission; a proportion of these find their way into prison for petty crime and are there certified. The difference between the Census returns and those of the Lunacy Commissioners was in 1871 equal to 17·7 per cent.; in 1881 it had fallen to 13·5 per cent.; and in 1891 it had sunk to 10·8 per cent. It is therefore obvious that a process of steady absorption of the unregistered reserve of lunatics in the country is going on, which will in a measure account for the ever increasing numbers coming under the official cognisance of the central department. The Commissioners also point out that while in the general population there has been a considerable increase in the number of persons at those ages when the greatest liability to attacks of insanity is known to prevail—viz., from twenty to forty-five—there has been a marked diminution in the ratios among the insane at those ages. This also goes to prove that accumulation, especially of old cases, and not fresh production, has been the most influential factor. In addition to the causes already mentioned, the Commissioners in their general conclusions enumerate greater accuracy of registration; extended views as to what constitutes insanity requiring confinement; the greater density of population in the large towns and the decrease of home industries, making it less and less possible to retain at home persons suffering from even the less severe forms of insanity; and the increased treatment in asylums of temporary attacks of alcoholic insanity. The report, on the whole, is distinctly re-assuring, and the Commissioners are to be congratulated on an effective piece of work. With the gradual absorption of the unregistered reserve within the official fold it is to be hoped that there will be a diminution in the yearly increase of numbers chronicled in each successive Blue-book. Such a result is devoutly to be wished for, not only to allay the natural anxiety in the public mind, but to reduce the growing burden which bears heavily on the public purse.

THERE is a very excellent publication commonly called the "Royal Red Book," issued by Messrs. WEBSTER of Piccadilly, and according to a circular recently sent out it has been suggested to that firm that a list of physicians and surgeons practising specially should be published in their "Royal Red Book," as such a list is in no

Hosted by Google

other work of reference and is greatly required by the public. Messrs. WEBSTER cannot, however, undertake to publish this list unless the additional matter is likely to pay for itself. So far, then, we have a purely commercial statement to which no objection can be taken. Messrs. WEBSTER may think that an addition of this kind will enhance the attractions of the "Royal Red Book." It may be a challenge to the new publication, "Who's Who?" and we cannot be surprised that they count the cost before entering upon this departure. But Messrs. WEBSTER'S circular continues: "We therefore propose to offer the publication of this information against the names in the Street List, the Alphabetical List, and the Special List (under the names of the diseases) of such as may desire it and are willing to subscribe to the book in accordance with the enclosed order. The sum mentioned will cover the insertion in both the editions of the year and a copy of one edition only." The sum mentioned is a guinea, and for this the name of the physician or surgeon practising specially can be inserted.

We do not fancy, judging by the numerous letters we have received from various members of the profession to whom the circular has been sent, that Messrs. WEBSTER will get many, or, indeed, any, favourable answers; nor can we understand how they could have even thought that the members of the medical profession would assist in the compilation of such a list. At all events, we have received copies of the circulars accompanied by damnatory letters from the leading members of every branch of the profession. After all, the fault lies with the public, who seem to think that the science of medicine nowadays is as it used to be in ancient Egypt, where, according to HERODOTUS, as rendered by an old translator, "Physicke is so studyed and practised with them that euery disease hath his seuerall phisition, who stryueth to excell in healing that one disease, and not to be expert in curing many: where of it commeth that euery corner is full of Physitions. Some for the eyes, other for the head, many for the teeth, not a few for the stomacke and belly. Finally, such as are of knowledge to deale with secret and priuy infirmities." No doubt the average patient would like to have a list carefully drawn up of "throat doctors" and "liver specialists" as he calls them, but the public ought to know better. It is perhaps to be regretted from one point of view that Messrs. WEBSTER'S proposition cannot be accepted, not only by the medical profession, but also by the sister callings of divinity and law, for the "Royal Red Book" would then become as interesting a work as a modern romance. We should then have as typical entries:—"The Rev. ——, specialist in domestic troubles; advice given as to the best way of getting on with a large family of unmarried daughters"; or "Mr. ——, specialist in criminal trials; special attention given to burglars and highway robbers, with or without violence." But, seriously, the descent to Avernus is all too easy, and the transition from the heights of the "Royal Red Book" to the depths of the gilded car and brass band might come about, if a protest were not entered against the possibilities of such methods of advertisement as Messrs. WEBSTER have—we feel sure unwittingly—offered to the profession. Human nature is weak.

Annotations.

"Ne quid nimis."

AN INTERESTING CEREMONY.

ON Monday afternoon last, at the Royal College of Surgeons of England, a portrait of Lord Lister from Mr. Ouless's brush was formally presented to the College on behalf of the subscribers. Mr. Davies-Colley, in making the presentation, drew an eloquent picture of the effects of the use of antiseptics upon hospital practice, upon the mortality after severe wounds, and upon surgical science and procedure generally, and congratulated Lord Lister upon the double recognition of the value of his work shown by his election to the Presidency of the Royal Society and his elevation to the House of Lords. The picture having been unveiled, Sir William MacCormac, the President of the College, accepted the gift on behalf of that body, expressing the great satisfaction that it was to the Fellows and Members to hang within their walls this portrait of one who had done so much to advance scientific surgery. Lord Lister expressed his sense of the honour that the College had done him in accepting his portrait in terms of equal modesty and felicity. In reference to his peerage he said that, while he was duly sensible of the distinction that Her Majesty had been graciously pleased to confer upon him, he was glad to remember that the movement which had resulted in Mr. Ouless's picture had been set going before that distinction had been thought of, so that the portrait must be regarded as a tribute to the truth and importance of antiseptic principles. Lord Lister then quoted from a pamphlet which had been sent him by Dr. Coley of New York, in which it was stated that in 360 operations for the radical cure of hernia undertaken with antiseptic precautions only one death had occurred, that death apparently not being due to the operation. Such results, he considered, "must cause gladness in the heart of any man who loves his fellow men."

MEDICAL MEN AS EXPERT WITNESSES.

THE Society of Medical Jurisprudence in America has taken into consideration the existing methods with regard to medical expert testimony, and the New York Academy of Medicine has passed a resolution empowering the president to appoint a committee to investigate the subject of medical expert testimony as now given in courts of justice and to make such recommendations as might seem appropriate. This matter of medical evidence is exciting much interest amongst professional circles in the States at the present time and is arousing much partisan feeling. Some of the opponents of the system go so far as to say that under the existing *régime* trials both criminal and otherwise are rapidly becoming mere farces in which the lawyer, his hired expert, and the criminal or plaintiff play the leading parts. In America the medical man is much more frequently called as a witness than in England both in criminal trials and civil actions, and many practitioners regard this giving evidence as one of the most lucrative branches of their calling. The reasons for this condition of affairs are, so far as civil actions are concerned, that railway and street-car accidents are appallingly common. The railway accidents are chiefly owing to the fact that level crossings, where insufficient precautions are taken to prevent mishaps, are in existence in very many of the large towns. The street-car accidents are due to the rate of speed at which these cars travel through crowded streets (this remark applies particularly to New York). When an

Hosted by Google

individual is maimed by one of these means an action for damages is invariably brought against the company controlling the line, unless the injuries were incurred too clearly through the sufferer's own fault. If the injured person be in poor circumstances a medical man is first consulted, who, if he considers that there will be a good chance of mulcting the company in substantial damages, recommends the patient to apply to a lawyer. An action for damages to a large amount is brought against the company, the lawyer stipulating that if the case be brought to a successful issue he shall receive half the amount, the medical man taking a proportionately large fee. In criminal cases the lawyer and medical man work together in a similar way. It is contended by the opponents of the system that under such circumstances the evidence of the medical expert is too often biased, and that he is inclined naturally to conceal that part of the truth which might bear unfavourably upon his side of the case. This state of things, for obvious reasons, is impossible in England; but on one point perhaps a salutary lesson as regards the giving of medical evidence might be learned from America. Conflicting evidence is almost unknown in the States, and medical men work together for the most part harmoniously.

"BUBONIC PLAGUE IN BOMBAY."

UNDER this title a paper was read by Dr. A. G. Viegas at the meeting of the Grant College Medical Society on Nov. 24th, 1896. After referring to some points of resemblance and of difference between the disease as observed in Bombay and other places, the writer considered very fully the means by which the disease may have been imported from other districts. Sugar and dates have been blamed as a means by which the plague was imported, but if this had been the case it is strange that the infection had never come from Bagdad and Bassora before and also that several districts in which the inhabitants had consumed these articles of diet remained perfectly free. Again, it is said that possibly the clothes of the sick or the dead from the plague in China might have been brought over to Bombay tied up in a bundle, but Dr. Viegas had not been able to elicit anything that might lend any support to this supposition. It has also been said that rats sick from the plague came by steamers from Hong-Kong, that the Hong-Kong rats gave the plague to the rats in and about the docks in Bombay, and that the fouling of the grain by the plague-stricken rats communicated the disease to the people who had the handling of the grain. Here, again, other facts, such as the time of the year, did not lend support to this theory. Then it is said that the disease was due more to poisoned grain than anything else; but even those who were biased in favour of this theory on repeated inspections of the grain "go-downs" failed to find any poisoned or unwholesome grain that might support this theory. Another widely spread supposition was that the grain storage in the Port Trust Estate was chiefly responsible for the outbreak. Dr. Viegas's own views on the subject are that the disease was due to the accumulated filth in the sewers of the Port Trust Estate—accumulation of putrefying matters in these drains. These drains are choked with dirt, especially organic dirt, such as fæcal matter, decomposing urine, &c., in large quantities—the untouched accumulations of nearly a quarter of a century. Dr. Viegas adds, however, that the most patient and persevering inquiries have not resulted in enabling him to make the remotest or vaguest guess as to the importation of the plague. He believes that if the Port Trust Estate had been sanitary it could never have got a foothold there, and he believes that the plague bacillus, if it had not been existing latent there, must have been brought more than once to Bombay, but could not flourish for want of suitable soil. Last year the insanitary condition of the Port Trust Estate drains reached, so to say, a climax, and afforded a suitable nidus for the growth of the plague bacillus. The meteorological conditions are then fully considered; the social position, sex, and age of those attacked; then the channels of entrance of the bacillus into the human system, its contagion and incubation. Next a full account of the symptoms is given, all forming extremely interesting and instructive reading, but we have not space to enter more fully on these points here. The mortality was very high. During the first four weeks of the outbreak it ranged between 95 and 99 per cent., but later it was between 85 and 90 per cent. Ordinary treatment was unsatisfactory; but should it prove a fact that Dr. Yersin's plague serum is an effective antidote to the poison a much more hopeful view may be taken. Prophylactic treatment by isolation, disinfection of excreta and clothing, and suitable disposal of the dead is, of course, of the utmost importance.

A DIAMOND JUBILEE STAMP.

MUCH consideration has been given to the problem of how to place it within the means of everybody in London to contribute to the form of commemoration for London approved by the Queen as embodied in the Prince of Wales's Hospital Fund. As the easiest and readiest way of enabling people of all classes with the minimum of trouble to subscribe to the Hospital Fund the Prince of Wales has approved a design for two stamps of the face value of 1*s.* and 2*s.* 6*d.* respectively, which has been prepared by the Government contractors, Messrs. De la Rue and Co., who have kindly given the blocks and drawings free of charge. The wholesale distribution of these stamps has been undertaken by Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., Limited, of Stationers' Hall-court, E.C. The stamps will be ready after Easter, when full particulars will be published. The issue will be strictly limited in number and no re-issue will be made. The stamps may be procured through any bookseller, newsagent, stationer, or stamp-seller. The design of the stamps is artistic and beautiful, and, apart from their popularity with the smaller subscribers to the Prince of Wales's Hospital Fund, they are calculated to excite great interest amongst philatelists, of whose society H.R.H. the Duke of York is the President.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE HEALTH OF THE ARMY.

WE would call attention to the report of the Committee of the Royal College of Physicians on this subject (vide page 980). Any representaation from so important and independent a body on such a question cannot fail to carry weight with the public and the Government, and it will be seen that the College speaks with no uncertain sound. Not only have the members of the Committee made themselves acquainted with the subject by a reference to a number of official and other reports and publications, but the President of the College and some of their number proceeded to Netley and personally inspected the sufferers now under treatment for syphilitic disease in that institution and ascertained for themselves the nature and type of their maladies. Almost every variety of constitutional syphilitic disease was, we are told, represented, those of a virulent form being very numerous and the results in many cases deplorable. The large majority of these patients had come from India; and it is difficult, the report says, to describe the painful impression made by the inspection of these sick soldiers. The College is emphatically of opinion that the amount of syphilis among the European troops serving in India has enormously increased of late years, that it is a matter of serious moment calling for the gravest consideration, and that some efficient means of dealing

Hosted by Google

with it should, if possible, be devised and applied. The report is a very weighty and well considered one, and the recommendations and suggestions contained in it will, we believe, commend themselves to all who approach and consider the subject impartially. It is, as we have said, no party question, but concerns men of all parties on the grounds alike of humanity to the sufferers of both sexes, State policy, and the well-being of society. The present state of things in India is, it must be admitted, very lamentable, and we trust that the action of the College will serve to strengthen the hands of the Government in any steps they may propose to take in regard to it. The recommendations of the College have the merit of being reasonable, practical, and moderate, and such as most people will regard as indispensable precautionary measures, if we are to make any successful attempt to cope with the evil in question. We entirely concur in the opinion of the College that power should be given to the Government of India to take such steps for its mitigation as they may be advised by those best acquainted with all the social and local conditions of that country.

"NATURE POETRY."

MR. W. J. C. MILLER, the Registrar of the General Medical Council, has reprinted a delightful little essay, originally contributed to *Nature Notes*, on "Nature Poetry." At this time of the year, when fickle Spring displays her caprice, it is pleasant to read such extracts from our sweet singers as the inimitable couplet of Tennyson, describing the song of the thrush:—

> "Summer is coming, summer is coming, I know it, I know it, I know it;
> Light again, leaf again, life again, love again, yes, my wild little poet."

But the essay is more than a series of extracts, it is a masterly appreciation of the spirit in which the poets of Nature have sat at the feet of "the dear old nurse" to turn over the pages of her story-book and listen to the tales she had to tell them. Although we may not know the exact *modus operandi*, it is quite certain that the mind plays an important *rôle* in the conservation of the body, and when the latter threatens to be overwrought by care and worry, and it is impossible or inconvenient from

> "Smoke and turmoil fly
> To seek a purer air and brighter sky,"

the mere reading about the pleasant sights and sounds of the country cannot but have a beneficial influence.

TREATMENT OF ECTOPIC PREGNANCY BY VAGINAL PUNCTURE.

DR. KELLY has recently brought this method before the Johns Hopkins Hospital Medical Society.[1] His practice had always been whenever extra-uterine pregnancy was recognised, whether ruptured or unruptured, to perform laparotomy at once. Having a patient who was too weak for this treatment, he punctured the vaginal vault with scissors and cleaned out the clots. Recovery followed. In another case, having performed laparotomy, he found the intestinal adhesions so intimate with the sac and so well walled off that he determined to make a vaginal puncture. Having introduced his finger within the abdominal incision to guard against encroachment on the abdominal cavity, he made a free opening into the vaginal vault, through which the wound was drained. This patient also recovered. He has now records of ten cases, in all of which convalescence was rapid and smooth and without marked suppuration. He regards the operation as especially satisfactory in that the patient has simply been relieved of the abnormal products without losing any normal pelvic structures. He now operates as follows. After an accurate diagnosis, outlining the sac and its relations by abdominal and rectal palpation, and after careful vaginal palpation to determine the proximity of the sac to the upper vaginal wall, a point is located behind the cervix in the vaginal fornix close to the sac and a pair of sharp scissors are plunged upwards in the direction of the pelvic axis. The scissors are then opened, and some of the fluid blood usually trickles out at once. Larger scissors are then introduced if necessary and the opening widened by withdrawing them with the blades open. It is important to have a large opening both for the purpose of getting two fingers in to clean out the sac and for good drainage afterwards. The sac must be delicately cleaned out and everything brought away down to the shell of the sac and surrounding adhesions. In one case he brought out a well-defined Fallopian tube cast. Irrigation follows, after which the sac is plugged with gauze, which is left in for several days or longer, and then the wound is washed out daily until it closes. There is one danger to which the patients are liable—hæmorrhage from the degenerated villi. His practical experience has shown that this is not imminent. In nine cases there was no hæmorrhage of any moment after cleaning out the sac. In one, however, it was so active that he had to open the abdomen and extirpate the sac. Anyone, therefore, who undertakes vaginal puncture must be prepared to perform laparotomy. Another danger is that the sac may rupture into the abdominal cavity, as the walls are quite thin in some cases. This has not occurred in any of his cases, but in one the douche nozzle was thrust through the sac into the abdominal cavity and a couple of quarts of boric solution introduced. He had to open the abdomen and wash out the solution. The patient made an excellent recovery. He regards his plan as not only an important departure in the treatment of ectopic pregnancy, but also as an index of the line of progress in the general domain of gynæcology. He uniformly treats all pelvic suppurations in the same way where he thinks he can get at the pus and establish good drainage. The present method is, he says, to remove the uterus by the vagina. He always insisted that he could get as good drainage without doing this.

[1] Bulletin, November and December, 1896.

PARISH MORTUARIES.

ON March 25th Dr. Thomas E. Hughes introduced at a meeting of the Wandsworth Vestry an admirable motion, which, we are glad to say, was carried unanimously—namely, that the vestry should advocate the desirability of there being a suitable mortuary and coroner's court erected and maintained in and for the parish of Wandsworth. Dr. Hughes made a powerful and earnest speech in support of his motion, laying special stress upon the need for reverence. "Among the problems of mankind," he said, "not one stands out more prominently than this—how, in a nation, parish, or family, to inculcate the virtues of reverence and self-respect among its different members." The present mortuary of Wandsworth is a miserable hovel about eight feet square; and, putting aside for the present any question of reverence or decency, we must ask, How is it possible to conduct a post-mortem examination either in safety or so as to afford any information in a place of this kind? Reverence is a quality sadly to seek in these democratic days, it went out with the spread of modern education and the baleful doctrine of "I'm as good as you and better." Let anyone notice a funeral passing along the street; not one person in a hundred will take off his hat or show any signs of reverence at all. A mortuary should not be a mere shed; it should be a home for the dead and should be divided into two portions—the mortuary proper, with decent fittings, and a room for post-mortem

Hosted by Google

examinations. With regard to the second part of Dr. Hughes's motion, a proper coroner's court is a necessity. It is most unseemly that a judge should have to inquire into what is and ought to be considered a most solemn matter—namely, how someone came by his death—in a public-house. The questions coroners have to decide are surely more important than a question involving £100 in money, and yet the latter is adjudicated upon with an amount of legal ceremony quite out of proportion to the matter at issue. We hope Wandsworth will act promptly upon the resolution of its vestry.

INDIAN MEDICAL SERVICE DINNER.

THE officers of H.M.'s Indian Medical Service have resolved to hold an annual departmental dinner in London. We understand that there will be a large gathering of the service at the first dinner, which will be held this year on May 20th at the Café Monico. The chair will be taken by Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., and amongst those officers on leave and on the retired list who have intimated their intention of being present are Surgeon-General Sir A. Christison, Bart., Surgeon-General J. M. Cuningham, C.S.I., Q.H.S., Surgeon-Major-General W. R. Rice, C.S.I., Q.H.P., Surgeon-Major-General W. R. Hooper, Sir Guyer Hunter, K.C.M.G., Q.H.S., Deputy Surgeon-General Sir Joseph Ewart, Sir Trevor Lawrence, Bart., Surgeon-Major Sir George Robertson, K.C.S.I., Surgeon-Colonel Roberts, Surgeon-Colonel Costello, and Brigade-Surgeon-Lieutenant-Colonel Keegan. Officers who have not already intimated their intention of joining should do so without delay to the hon. secretary, Mr. P. J. Freyer, 46, Harley-street, W.

THE GREAT LESSONS TAUGHT BY BACTERIOLOGY.

THOSE great processes in nature in which, as modern investigation has shown, bacteria play so important a part were the subject of a very instructive lecture delivered by Dr. Sims Woodhead at the Institution of Civil Engineers on March 18th, when Mr. Wolfe Barry, C.B., F.R.S., occupied the chair. The occasion was an extra meeting of the institution devoted to the hearing of the James Forrest Lecture. Dr. Woodhead began by observing that people are prone to take a somewhat one-sided view of the great facts which investigation brings to light, and that this has never been more forcibly illustrated than in the general way of regarding the work done by bacteria. The tendency is to accept them as the ultimate causes of certain forms of deadly disease and as promoting the evolution of putrefactive products; whereas, as a matter of fact, they are instrumental in keeping the world sweet and clean for its inhabitants and in maintaining a constant circulation of organic matter from the dead condition to the living and from the living to the dead. It is interesting to reflect that without the aid of bacteria the human race would be unable to continue its existence—the animal and vegetable world would long since have perished from sheer inanition or starvation, and the work of the world as a great laboratory would have come to a standstill. Bacteria, as is being found out every day, may be engineered for man's good, so long as they are kept under intelligent control, and once their habits are understood they prove to be the most perfect servants that can be obtained. The lecturer proceeded to trace the history of bacteria and their discovery, and the developments up to the present time which have followed upon a close and exact study of their behaviour. The functions of bacteria in the great natural processes in their bearing upon sanitation were then dwelt upon; and, finally, the recent developments in regard to the wonderful ability of certain species of bacteria to appropriate the nitrogen in the air, through the medium of the soil, for the maintenance and sustenance of leguminous plants formed not the least interesting section of the lecture. It was remarked that so well defined were the results of the researches in this direction that cultivations of these organisms are now made for sale and kept in closed bottles for distribution to all parts of the world. There, when mixed with water and thrown over the soil, they immediately begin to do their work, and taking nitrogen from the air, which lends valuable assistance to that from the soil, they enable the plants, and especially those requiring large quantities of nitrogen for their full growth and development, to grow both more rapidly and more luxuriantly than they could do if unaided by this supplementary store. The relation of bacteria to disease was next touched upon, and the beneficial effects of fresh air and light accounted for by observations on the inhibitory action of these agencies upon such organisms. Dr. Woodhead concluded his lecture with the following words "As yet no one can say that we have reached eve a resting stage, and it behoves all those who desire to see advances made in the treatment and prevention of disease—whether in the department of protection and cure, with which medicine is specially concerned, or in the preventive department, with which civil engineers have to deal—to continue to follow closely every new fact and every fresh theory arising out of new observations in order that bacteria and the forces with which they are endowed may be made our well-disciplined servants, instead of being allowed to waste their energies as our uncontrolled and uncontrollable masters."

THE TREATMENT OF SUNSTROKE BY ICE.

IT is a fact now generally admitted that there comes a stage in the treatment of many diseases when the reduction of temperature in itself is a curative measure of great value. This is more or less true of pyrexia in general, but it is most vitally true of hyperpyrexia. The means employed for this purpose may differ, but the principle which they obey remains unaltered. A series of cases of insolation published in the *New York Medical Journal* of March 6th, by Dr. N. R. Norton, are of value as teaching not only the utility of external cold when applied for this purpose, but also the success which may be expected from energetic treatment even in apparently hopeless cases. It may be remembered that the heat of last summer in New York was for a time such as has hardly ever been equalled. During the six days from Aug. 8th to 13th inclusive 110 cases of heat stroke were in hospital under Dr. Norton's care. Fifty of these patients had high fever, with, in the great majority of cases, severe brain symptoms, seven only being recorded as conscious and two as semiconscious on admission. The average rectal temperature in these was 104·5° F. The remaining forty-one were either delirious or comatose, with an average rectal temperature of 108·5°. The pulse, as usual, was of low tension in all. The treatment consisted in sponging and rubbing with iced water, an iced bath being also used as a rule and continued for periods varying from a few minutes to an hour, till the temperature had fallen several degrees. A further fall, sometimes with general depression, occurred after this, and was followed in most cases, after a varying interval, by a second rise. This was ushered in by fibrillar twitching, becoming convulsive, and was also reduced by the ice treatment. Cold thus applied and aided by friction appeared to act at the outset as a rapid and powerful stimulant. Recovery, when it occurred, was rapid, the patients leaving hospital after an average detention of thirty hours. The total result attained was most favourable in comparison with the high mortality associated with sunstroke, the number of deaths in these

Hosted by Google

fifty severe cases being only six, or 12 per cent. Necropsies in five fatal cases showed more or less congestion of the lungs, and, as a rule, of the pia mater, sometimes with ecchymosis and softening of the brain or spinal cord. It is noteworthy that the use of alcohol seemed to have exerted a direct and unfavourable influence in predisposing to sunstroke.

THE PROFESSOR OF ANATOMY AT KING'S COLLEGE.

PROFESSOR ALFRED W. HUGHES, of University College, Cardiff, has been appointed Professor of Anatomy in King's College. His four years' occupancy of the anatomical chair at Cardiff, during which time he had the arduous task of organising the anatomical department of the new medical school, and his previous appointment (also held for about four years) as lecturer on anatomy in Edinburgh, have supplied an excellent practical training for the more important position of a metropolitan teacher. His published works afford evidence that he possesses both literary ability and a capacity for original research.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

THE directors of the Caucasian lines of railway have made arrangements for a short tour in the Caucasus for members of the Congress, of which the following are the details. A special train, with accommodation for 100 passengers, will leave Moscow at the close of the Congress for Kislovodsk, in the northern Caucasus, where a stay of two days will be made to enable members to visit the group of mineral watering-places of which this is the centre. From Kislovodsk the train will go to Vladikavkaz, the terminus of this railway. Here there will be a choice of two routes. One party will proceed to Tiflis by the Georgian military road, which passes through some of the most beautiful scenery in the Caucasus. The other party will proceed to Petrofsk, a port on the Caspian Sea. Thence a special steamer will convey them to Baku, where a stay of a day will be made; and they will then proceed by train to Tiflis, where they will rejoin the first party. From Tiflis all will proceed by train to Batoum on the Black Sea, where one day will be allowed to see the town and neighbouring tea and cotton plantations; and from Batoum by steamer to Sukham, New Athos, and Novorossüsk, whence they will return by special train to Moscow. The cost of this circular tour will be only 150 francs (£6). There will be no hotel expenses, as arrangements have been made to enable the travellers to sleep each night either in the train or on board a steamer. The only extra expense will be for meals, which are not included in the fare. The round tour will take just a fortnight. If more than one hundred members of the Congress wish to make the tour a second train will be run.

THROMBOSIS OF THE LEFT VERTEBRAL ARTERY.

IN the *Rivista Clinica* Dr. Giuffré of Palermo has published an interesting case, of which an abstract appears in the last number of the *Neurologisches Centralblatt*. The onset was marked by sudden weakness of all the extremities, especially on the left side, slight left-sided ptosis, paresis of the left frontalis muscle, paralysis of the orbicularis oris on the two sides, slight fibrillary twitching of the tongue, and disturbance of swallowing and phonation. There was interference with the sensibility for pain and for cold on the right half of the body except on the face, and some impairment of taste. Respiration was interfered with and afterwards became of the Cheyne-Stokes variety. Death took place four and a half months after the onset, and at the necropsy there was found thrombosis of the left vertebral artery extending forward into the basilar and backward into the anterior spinal artery and the inferior cerebellar artery. The softening embraced the region of the ninth to the eleventh cranial nerves, including the nucleus ambiguus, a part of the ascending root of the fifth nerve, part of the olive and of the cerebellar tract. There was also a small patch of softening in the region of the auditory nucleus and another in the cerebellar hemisphere. The case is a very interesting one, especially in reference to the sensory condition which was present, a condition similar to that which has been observed in other cases of the same character.

A FRENCH MEDICAL SOCIETY ON CERTAIN ETHICAL QUESTIONS.

DIFFICULT problems in medical ethics are constantly coming before many busy practitioners—questions, too, which often have to be answered categorically on the spur of the moment without any opportunity of consulting a brother practitioner or a legal adviser. It is therefore interesting to see what view others take of their duty in difficult cases. The following questions were propounded recently to a French medical society:—1. A young woman put her illegitimate child out to nurse, and after a time, thinking that it did not thrive as it ought, took it away and gave it into the charge to a second wet nurse, whom it infected with syphilis. The medical man attending the woman informed the mother of this, and she undertook to be responsible for his fees, which she paid for a time—that is to say, until she took the child away; but although the woman required further treatment she refused to pay any further fees for her. The woman consequently asked her medical man (who, it should be stated, had also attended the child) to give her a certificate that she had been infected by the child. The question asked the society was, Should this certificate be refused? The reply was in the negative. 2. A lady sent her maid-servant to a doctor, who found she was suffering from tuberculosis. The question asked was: Should the medical man reveal his diagnosis to the lady when consulted by her as to the possibility of retaining the servant? The majority of the society replied in the negative. It is possible that if this second question had been propounded at a meeting of an English medical society a different answer would have been given, but it must be remembered that in France violation of professional secrecy is a crime, not merely a ground for a civil action as with us.

SELF-GOVERNMENT AND THE PLAGUE.

FREEDOM is said, and rightly so, to be a priceless boon. But we can have too much of any good thing, and never has this somewhat trite saying had more justification than in recent events in Bombay. As early as September last the existence of plague was well known. A system of rigid segregation was drawn up by the Government and the municipality on the advice of a committee of medical men. As a matter of course, however, this pressed hardly upon certain members of the community, and the municipality, in the true spirit of Little Pedlington, withdrew the restrictions. Nor were the Government blameless. Instead of quashing the municipality, they, to quote a writer in the *Times of India*, sat with folded hands. The result was a great increase in the tale of mortality and a distribution of infection far and wide. We are not among those who write and talk about India as if it were England. We are well aware of the many difficulties which beset the government of an Eastern city. Oriental customs, habits, and religions are every one and all opposed to Western ideas, and it is not only a bad policy, but an almost hopeless one, to fight against them in ordinary matters.

Hosted by Google

But in a matter of life and death, a matter involving the lives and prosperity of thousands, it is the duty of a Government to govern. Supposing there had been a riot, as was feared by the authorities, are what an eminent statesman called the resources of civilisation extinct? Far fewer lives and property would have been lost if segregation had been ruthlessly carried out than has been the case under the system of *laisser faire* which has been adopted. The arrangements for nursing and the hospital accommodation seem to have been grossly inadequate; but recent advices show that the authorities have, if tardily, entered upon a course of energetic measures. They seem now to have remembered what they must have known—that Orientals respect a real Government, and that a little wholesome despotism is sometimes worth pounds of so-called freedom.

THE HEALTH OF THE ARMY.

THE EARL OF ONSLOW, in a communication to the *Times*, has directed attention to a matter to which we have more than once adverted. In spite of the clear and precise statement of Lord George Hamilton, there still exists apparently some misapprehension and confusion in regard to the term "admissions" employed in Army statistical returns. As Lord Onslow explains, the numbers of *admissions* are not identical with the numbers of *men* admitted, because some men are admitted more than once in the year; and he calls attention to the footnote to paragraph 11 of the report of the Departmental Committee in evidence of the fact that this difference has not been overlooked, but expressly referred to. In the case of venereal disease it appears from figures supplied by the principal medical officer in India that the number of men admitted in 1895 was rather more than three-fourths of the number of cases—i.e., admissions. If therefore, adds Lord Onslow, the ratio of admissions to hospital in 1895 be 522 per mille, the total number of men admitted would be about 391 per mille. The report of the Departmental Committee states that in 1895 an average of 45 men per 1000, or 3200 in a force of 71,031 British soldiers in India, were constantly in hospital for venereal disease.

BERI-BERI IN AFRICA.

DR. LASNET, of the French Colonial Service, who acquired his experience while on duty at the Dakar prison in Senegal, Western Africa, has written an interesting report on beri-beri.[1] The total number of prisoners under his observation during the year 1895 was 647, of whom 52 were Europeans, the remainder being natives of the region. The two classes are said to have lived under identical conditions with regard to both food and lodging; but whereas no European or mulatto contracted beri-beri there were 45 cases among the aboriginals, the men in the military division being three times more liable to the disease than their civilian congeners; 149 military prisoners caused 24 admissions during the twelvemonth, but out of 446 civilians only 21 were attacked. Length of residence in the gaol and want of occupation, together with overcrowding, defective ventilation, and utterly inadequate provisions for cleanliness and the removal of filth and ordure were the chief determining causes. Of thirty-two soldiers who had been confined upwards of five months two thirds became affected. The civilian prisoners used to be sent out to work in the vicinity, but the enlisted men claimed exemption from the *corvée* and lay idle all day long wrapped up in their blankets. The affection generally commenced towards the third month of incarceration with malleolar œdema and constipation, attended by depression of spirits, varying from listlessness to profound apathy. When fully established the usual symptoms of the disorder were well marked; non-pitting dropsy, paresis of the lower limbs mainly implicating the extensor muscles, diminished reflex excitability, partial cutaneous anæsthesia, and the characteristic dragging gait. Towards the end unquenchable thirst was a most distressing concomitant, the unfortunate sufferers complaining of a feeling as though fire were consuming their vitals. At no stage, however, were febrile phenomena to be detected, the writer's words on this head being most precise—"not the slightest reaction manifesting itself in fever or by inflammatory developments; in all cases the most complete apyrexia." The only treatment of any permanent efficacy was an entire change of scene. When the disease made its appearance for the first time compulsory exercise was invariably followed by an amelioration of symptoms, but if the patient remained in prison a relapse ending fatally was sooner or later certain to supervene. Taking advantage of an article in the prison regulations, th principal medical officer, Dr. Clarac, recommended the discharge of twelve prisoners suffering from beri-beri in order that their lives might be saved. The proposal, which required Ministerial approval, was duly sanctioned; but before the official intimation reached Dakar three months had elapsed and five out of the twelve patients were dead. The seven survivors were at once set at liberty, and eventually all of them recovered. Dr. Lasnet is of opinion that telluric and meteorological influences have not much to do with the production of beri-beri. The buildings constituting the prison are well exposed to the prevailing winds and stand on ferruginous volcanic soil from two to three metres in depth, beneath which an argillaceous stratum slopes downwards towards the sea, thus rendering all water-logging impossible. He attributes the blame solely to the unhygienic conditions under which the prisoners at Dakar are allowed to live, but the chief determinator of the disease is the lack of suitable employment.

[1] Published in Archives de Médecine Navale et Coloniale, February, 1897.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

THE *Birmingham Gazette* of March 25th contains a notice of the fifty-sixth annual report of the committee of the Queen's Hospital, in which the governors are congratulated on an increase of 120 in the in-patients treated and of 312 in the out-patients. The whole number of in-patients was 2109, that of out-patients 28,120 We cannot join in the congratulations to the governors on the increase of out-patients. One of the best proofs of a well administered hospital must be acknowledged to be a steady and decided annual decrease in the number of out-patients, for two reasons—first, that the treatment of such promiscuous crowds of out-patients is demoralising to all but the poor among them and unjust to subscribers, who do not give their money for such purposes; and secondly, because it hampers and limits the accommodation of the hospital for really urgent cases. A striking and painful illustration of this is given in a leading article in the same number of our contemporary. It refers to an inquest at which the following facts were stated to have been brought out, though we hope there is some mistake or explanation. A cyclist with a fractured skull was taken to the Queen's Hospital, and the house surgeon, acting on a rule, declined the treatment of the case as a bed was not available. This in a hospital with accommodation for treating 28,000 out-patients in a year! We gather that the unfortunate man was sent away to the General Hospital, which, as our contemporary suggests, might have acted in the same way to the dying man. No wonder that our contemporary threatens to reconsider its attitude towards hospitals where such helplessness is possible towards the most urgent cases. The whole system is being jeopardised

Hosted by Google

apparently in order that committees may boast of ever increasing numbers in their annual report.

A DANGEROUS OCCUPATION AT HOME.

A SHOCKING accident occurred in Halifax last week in connexion with the compounding of varnish with naphtha. It appears that the wife of a boiler "coverer," who for the purposes of his business used a varnish which was prepared at his home, proceeded to get the naphtha from a four-gallon bottle, and after using half a gallon of it she placed the bottle on the floor, when before she could insert the cork the contents of the bottle ignited, and "the flames seemed to go towards the fireplace." She shouted to her children to come out of the house, and then herself ran into the street. Directly afterwards there was a loud explosion, and the room was soon ablaze and the house well in the grip of the flames. Two children, aged respectively six and fifteen years, perished, and the body of one poor boy was found burnt almost to a cinder. The naphtha found in the cellar was examined, and the analyst reported that in applying the flash-point test the thermometer of the official testing apparatus did not reach a low enough temperature to record the point of inflammability. It was proved afterwards that the naphtha actually gave off an inflammable vapour at the freezing point of water. In view of this evidence the explanation of the disaster is simple. At the ordinary temperature of the room in the house the naphtha must have been literally distilling out of the bottle when the cork was removed, and the direction of a draught of air being naturally towards the fireplace the vapour was carried in a stream thither and ignited. Whilst entirely agreeing with the opinion of the jury, that "the manufacture, containing a dangerous compound, ought not to be carried on in a dwelling house," we would add that it is highly desirable that wheresoever such manufacture is carried on it should be done in apartments heated by steam or by hot water apparatus, and not, under any circumstances, in the vicinage of an open fire.

ACCORDING to a telegram which we have received from Bombay the Yersin serum treatment of plague has practically failed. So far the mortality has been 50 per cent. in the selected cases within forty-eight hours of the attack. The hospital mortality is stated to be 60 per cent. in all cases.

A SESSIONAL MEETING of the Sanitary Institute will be held at the Parkes Museum on Wednesday, April 7th, at 8 P.M., when a discussion will be opened by Dr. Henry R. Kenwood, medical officer of health of Stoke Newington, on 'Notification of Measles."

DR. LAUDER BRUNTON, F.R.S., has accepted an invitation from the Executive Committee of the International Medical Congress to give one of the general addresses at the forthcoming Congress in Moscow.

A NEW HOSPITAL IN OXFORD-STREET.—A new hospital, which is practically an extension of the Ings House Nurses' Coöperation and Nursing Institution, New Bond-street, was opened on March 22nd by Lady Harris at 180, Oxford-street. Lady Harris, who was accompanied by Lord Harris, Lady Bayley, Mrs. W. B. Gladstone, and others, said that much good work had been done at the Bond-street institution, which has six beds for paying patients; the new premises will accommodate nineteen patients, and will supply a want which is often felt by persons of moderate incomes when overtaken by sickness. At present there is a debt of £300, but it was hoped that in two years the hospital would be self-supporting

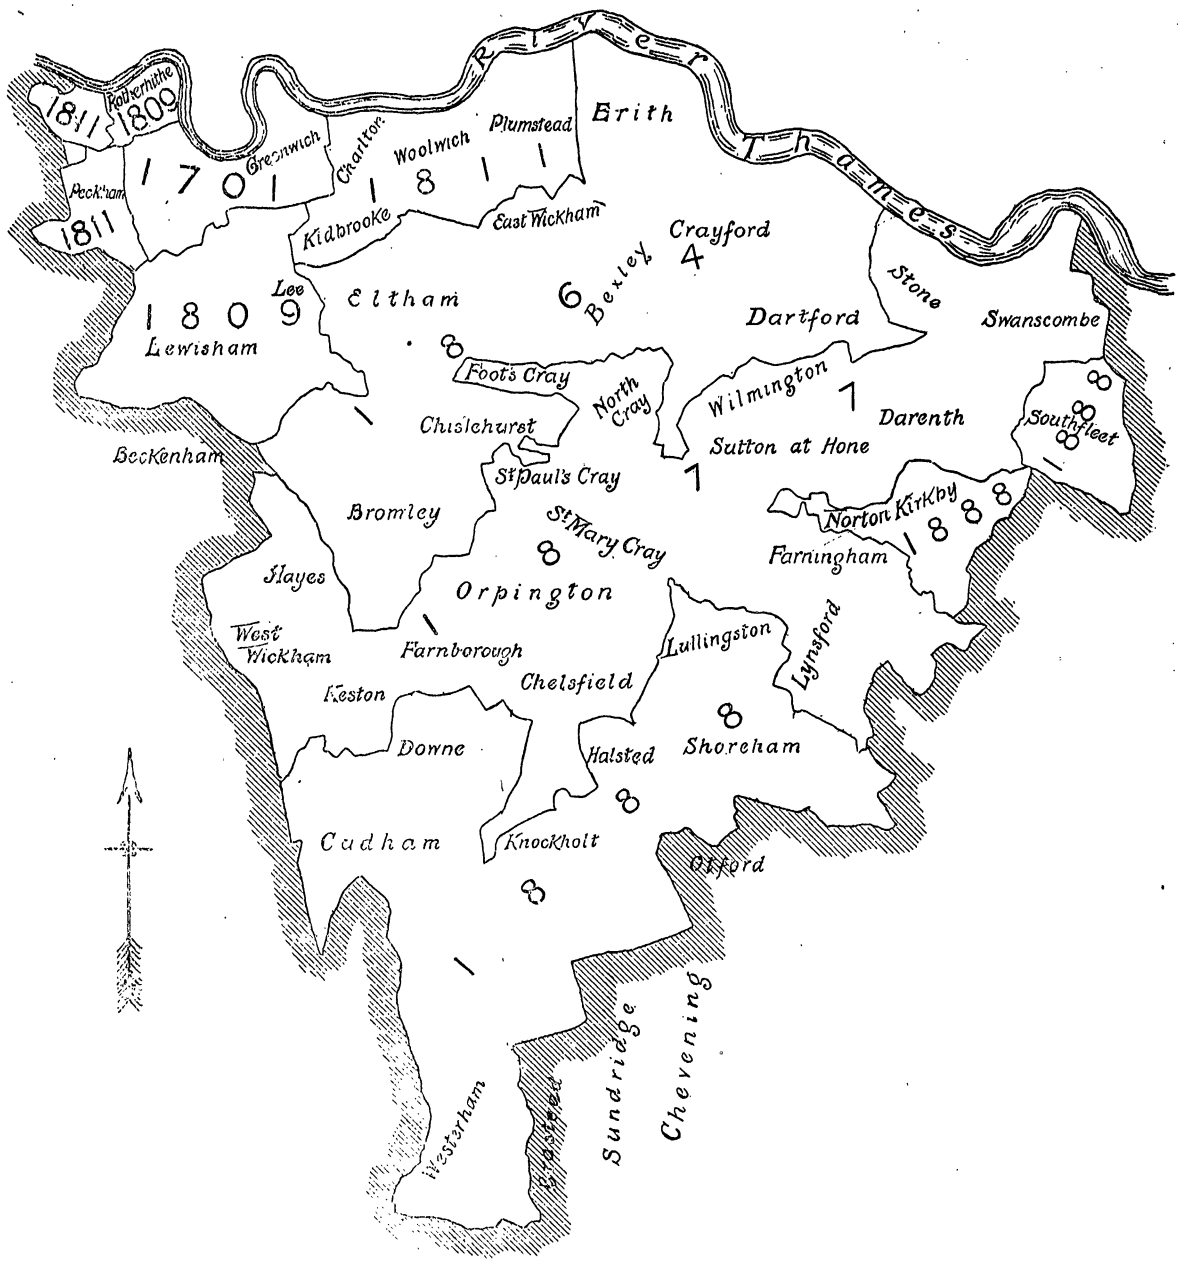
KENT WATERWORKS COMPANY.

History.

THE Kent Waterworks Company possesses the rights of an old-established institution which dates back to the reign of William III. The present Company has also absorbed quite a number of small undertakings which have been started at different times since (Fig. 1). In 1701 letters patent were granted at the request of the inhabitants of Sayes Court[2] and East Greenwich giving to the patentees liberty to break up streets and grounds in those places for the purpose of laying pipes to convey water, and a monopoly was granted for this work, all other persons being prohibited under pains and penalties for a period of 500 years from interfering with the water-supply in these parishes. The result of this privilege was that waterworks were made at Ravensbourne, and these continued to be worked till the year 1808. In the following year an Act was passed incorporating the proprietors of the waterworks, and it was provided that the Company should buy the letters patent which had been granted by William III. and the rights and privileges which belonged to them and the works which were already in existence. The Act of 1809 prohibited the Company from supplying water in such a way as to directly or indirectly affect those rights without the consent in writing of the people concerned or till the old waterworks were bought. Ultimately the patent was bought and "The Company of Proprietors of Kent Waterworks" became under the provision of the Act possessed of all the privileges, authorities, duties, and offices given by the letters patent. The manors of Sayes Court and East Greenwich included the towns of Greenwich, Deptford, and the adjoining districts, and under the Act of 1809 the authorised limits of supply were the two parishes of Deptford and the parishes of Greenwich, Lee, Lewisham, and Rotherhithe. A year before this Act of Incorporation was passed the Town Commissioners of Woolwich had obtained Parliamentary powers to supply the town of Woolwich with water, and in 1810 the commissioners came to an arrangement by which this work should be taken over by the Kent Company should the necessary sanction of Parliament be granted. The Act passed in 1811 authorised this transfer. The area of supply was thus increased to include Woolwich, Plumstead, Charlton, Bermondsey, Peckham, and Peckham-rye, and arrangements were made about the same time that the Company should supply various Government establishments. The Ordnance Department at Woolwich and the Artillery Barracks of the garrison were first supplied, and later contracts were made for the supply of the Royal Arsenal, the Admiralty establishments, the Dockyard at Woolwich, the Royal Observatory, the Royal Naval Hospital, and His Majesty's Dockyard and Victualling Yard at Deptford. As in the case of some other companies, the profits made were for a time chiefly used in the outlay necessarily involved in extending the area of supply.[3]

---



[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of Feb. 20th, 27th, and March 6th, 13th, 20th, and 27th, 1897, respectively.

[2] It may, perhaps, be permissible to leave dull details for a moment to recall the fact that the Royal Manor of Sayes Court is a place of considerable historic interest. It was granted by Charles II. under his great seal to John Evelyn, a second son of the then head of that family—a family which Surrey has, as in the case of the Onslows, attracted from Shropshire. Mr. John Evelyn, "a most ingenious and polite gentleman, well versed in useful learning," is best remembered by the world at large by the diary he left and by his book on trees. The family seat at Wotton, to which he afterwards succeeded, still shows the results of his love of practical gardening. At Sayes Court lived for a time Peter, Czar of Muscovy, generally known as Peter the Great.

[3] The early struggles of the Company are rather plaintively but hopefully referred to in a will of one of the proprietors dated 1815: "I am possessed of ..... shares in the Kent Waterworks. They originally cost £100 each. God knows how they will go on; at all events they will want time to grow. I therefore leave them to ....." The testator left the shares to his "opposite neighbour's" daughters.

In 1850 and 1852 Acts were passed enabling the Company to increase their capital. About the middle of the present century an establishment called the Plumstead, Woolwich, and Charlton Consumers Pure Water Company was started. A well was constructed, and the necessary plant was put up by the Company, which, however, afterwards became bankrupt, when the plant was bought by the Kent Waterworks Company. In 1860 the North Kent Company was started with an idea of supplying Dartford, Crayford, Bexley, Wickham, Erith, Eltham, Chislehurst, and Bromley. The business of this undertaking was taken over by the Kent Company in 1864, and at the same time fresh capital was raised, and a schedule of water-rates was prescribed. The Company's area now included the places just mentioned. In 1867 the Local Board of Dartford sold their waterworks, which were acquired by the Kent Company, and the Company's area was thus extended to a district having a total area of about sixty-eight square miles. In 1877 the Bromley Rural Sanitary Authority requested the Kent Company to supply their district, and the Dartford Rural Sanitary Authority made a similar request. The result was that the Kent Waterworks Act of 1877 was passed and extended the limit of supply to the following places—viz., Swanscombe, Stone, Darenth, Wilmington, Sutton-at-Hone, Farningham, Eynsford, Foots Cray, North Cray, St. Paul's Cray, St. Mary Cray, Orpington, Farnborough, Chelsfield, Keston, West Wickham and Hayes, and the portion of Beckenham known as Shortlands. The Company's district of supply was thus extended to an area of 120 square miles. In 1885 the Bromley and the Sevenoaks Rural Sanitary Authorities requested the Kent Waterworks Company to supply parts of their districts. The necessary Act of Parliament was obtained in 1888, and the Company's limits of supply were thus extended to an area of about one hundred and seventy-eight square miles, of which about thirty only are within the County of London, the remainder being in the County of Kent. When the Company as at present constituted began their business by taking over the Ravensbourne Waterworks the undertaking was a comparatively small affair.

The works were situated on the banks of the river and consisted of a pump which was worked by a water-wheel. The machinery was designed by Smeaton. The water was distributed through wooden pipes A few years later a pair of steam-engines were put up by Boulton and Watt, and these engines are still working. Unfiltered water was used till the year 1844, when the first filter bed was made, and in 1850 a subsidence reservoir was constructed, and more filter beds were constructed. The reservoir is still in existence; it is situated to the west of the river, but it has for years been disused as a source of water-supply, and remains as a piece of ornamental water in the garden of the engineer. The water of the Ravensbourne was insufficient to afford a supply, and in 1857 a deep well was sunk in the chalk. An abundant quantity of pure water was found, and from the year 1862 the entire district of the Company has been supplied by well-water. New wells have been sunk as occasion required. All of them are in the chalk, except the one at Westerham, which is in the lower greensand.

Geology of the District.

In the case of the metropolitan water companies of which an account has hitherto been given it will be remembered that, with one exception, the water used by the companies comes either from the River Thames or from the gravel beds near the Thames. The only well which has been referred to is the one at Streatham, which belongs to the Southwark and Vauxhall Waterworks Company. A full description of the strata cut through in making this well has been given in THE LANCET (March 27th, pp 902-3).

The Kent Waterworks Company derives all the water supplied from deep wells; it is therefore of interest to note the geological character of the district. The company's area is bounded on the north by the River Thames, and to the south it extends beyond the North Downs. A diagram (Fig. 2) shows the arrangement of the geological strata.

At the extreme south Westerham is on the lower greensand, a formation which contains extremely good water, much less hard than the water found in chalk formation. Passing northwards there is next a narrow layer of gault, an almost impervious clay formation; then farther northwards there is a narrow band of upper green sand. Still farther northwards is the range of the North Downs, which run in a direction nearly due east and west, the eastern end running to the sea just south of Deal. In a westerly direction the downs run just to the north of Reigate and Dorking to Guildford, and from the west of Guildford towards Farnham. Near Westerham the crest of the chalk escarpment is generally over 600 ft. above the sea level. The ground falls from the crest sharply to the south; towards the north and the north-east the slope is more gentle. The diagram (Fig. 2) shows the position of two of the chalk wells, at Orpington and Crayford, and the position of the river beds of the Cray, the Darent, and the Thames.

On the North Downs there are patches of clay with flints and loam. These patches are irregularly distributed. From Westerham to Orpington the section shown in the diagram runs in a north-north-easterly direction; from Orpington to Purfleet the section runs in a north-easterly direction. Between Orpington and the line of the London, Chatham, and Dover Railway there are springs. There are patches of lower tertiary beds between this point and Crayford, which is on the chalk.

The depth of the level of water in the chalk varies. For example, at the present time the level of the well at Orpington is about 60 ft. below the surface of the ground. In a dry summer the level has been as low as 90 ft. below the surface. In estimating the water-bearing capacity of a district like that described it is necessary to know not only the area but the amount of rainfall, and it must be borne in mind that to be on the safe side it is necessary to reckon only the percolation which would take place during a dry year. Through a chalk district water finds its way to the sea in different ways. Some of the water rises in springs which break out at the foot of the chalk escarpment; some of it in wet seasons breaks out in streams in the higher levels, but during dry periods these streams do not run at all. Some, again, breaks out in springs in the lower ground. Much water, however, passes in underground channels; through chalk its passage is slow. Some of this underground water passes through fissures and in the lines in which flints occur. It passes also in large amount through faults in the chalk, which are water-bearing channels. It may be remarked in passing that a well which happens to be sunk in the course of one of these faults will afford a bountiful supply; and headings which are made in connexion with the deep wells in the chalk are made more or less in the hope of coming across one of these channels.

The average of the rainfall over the district is estimated to be about 26 in. It is less than this over the lower ground, and at Greenwich is about 24 in., but on the higher levels it rises to 30 in. It is a difficult or impossible matter to determine how much of the rainfall is available for the supply of wells which are constantly pumped. At one time 6 in. a year of the total rainfall was supposed to be the amount which it was likely could be used. Later the estimate was considerably raised, when it was thought that as much as 12 in. might be available. The present amount of water used daily by the Kent Company is estimated at about 16,000,000 gallons. According to some evidence that was given before the last Royal Commission on the Metropolitan Water Supply it was stated that the Company's Parliamentary area would be likely to afford a supply of 30,000,000 to 40,000,000 gallons daily.

(To be continued.)

ANNUAL REPORT FOR 1895 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

SECOND NOTICE.[1]

HAVING dealt with the statistical portion of Mr. Shirley Murphy's report, we have now to consider the remaining portion, which relates mainly to the administrative action of the Central Medical Staff for the Improvement of the Public Health. There is no department of sanitary work in which the London County Council can more usefully engage than in that of directing, and in some cases stimulating, the sanitary operations of the forty-three local authorities which come under its jurisdiction. And there

[1] The first notice appeared in THE LANCET of March 20th, 1897.

Hosted by Google

is certainly no criterion by which the ability and tact of their medical adviser can be more justly estimated than by the degree of success which from time to time marks his attempts to encourage and develop local sanitary effort. Nor is this part of the county medical officer's duty by any means easy of fulfilment. For, in the first place, the fact must be considered that for a long period the numerous self-governing bodies of the metropolis have, under the title of "vestries," enjoyed practical independence in the execution of their sanitary functions. These bodies are therefore peculiarly averse to what they are prone to regard as outside interference, albeit this may be exercised by a statutory tribunal on which they themselves are duly represented. Again, it must be remembered that for many years past the forty-three vestries have been advised by as many separate medical officers of health, most of whom are men of high professional standing and long experience, who possess the confidence of their respective authorities. For the above-mentioned reasons the necessity will be apparent that the inter-relations of these local officers and the medical staff at Spring-gardens should be maintained on both sides with uniform consideration, patience, and good-will, if existing arrangements are to yield the best results. We notice with satisfaction the evidence afforded by Mr. Shirley Murphy's successive reports of the fact that in his own dealings with his numerous colleagues in the sanitary areas of London he has invariably been actuated by this sound principle. In the earlier years of his appointment Mr. Shirley Murphy had to depend on his own exertions exclusively. He possessed neither professional assistants nor staff, and, in fact, was compelled to make a position for himself and to organise a department which should eventually be competent to direct and control the vast sanitary machinery of the metropolis. It was not, therefore, until the year 1892, by which date the nucleus of a preventive department and staff had been provided, that Mr. Shirley Murphy felt justified in publishing his first annual report. Since that period, however, the administrative sanitary work of the council has progressed apace, and each successive report has borne additional evidence of the beneficial influence which the central office has exercised on the local authorities in the direction of sanitary progress.

By the Public Health (London) Act, 1891, it is provided that the London County Council shall pay a moiety of the salary of every metropolitan medical officer of health and sanitary inspector appointed or re-appointed after the passing of that Act. Up to the end of the year 1895 39 medical officers of health and 153 sanitary inspectors had been thus appointed or re-appointed. As the county council is bound to contribute to the remuneration of these officers, it of course follows that, in the first place, that authority and its medical department will possess, under legal sanction, the right of co-ordinating and controlling local sanitary operations; and, in the second place, that the local sanitary officers will be protected from capricious dismissal for fearless discharge of duty. It is greatly to be desired that this wholesome reform should ere long be extended to the large body of urban health officers acting outside the metropolis, many of whom are devoted entirely to the practice of preventive medicine, and perform functions even more onerous than those of any metropolitan officer of health, with the exception of the chief medical officer himself.

In the report before us is given an instructive example of the means by which a well-regulated central department can bring about desirable reforms in local sanitary administration. In the course of the year 1895 communications were addressed by the London County Council to seven metropolitan sanitary authorities calling attention in each case to the inadequacy of the local inspecting staff. One of the districts referred to having demurred to this charge of "making default," an assistant medical officer of the central department was instructed to make an inspection of the district and to report on its sanitary condition and administration. Dr. Hamer, who was selected for this duty, found that the inspecting staff of the district in question was as a matter of fact insufficient, and reported accordingly. This statement having been challenged by the vestry, who urged that the report had been made after insufficient inquiry, Mr. Shirley Murphy made a special communication to the county council on the merits of the case and on Dr. Hamer's local investigation. This communication was eventually forwarded to the Local Government Board. As a result we are informed that the vestry have already increased their staff of inspectors by the appointment of four additional officers. It is worth notice that although, as in the present instance, the action of the county council is wisely limited in the first instance to friendly representations to defaulting sanitary authorities, the council has abundant statutory authority under the Equalisation of Rates Act, 1894, to require compliance with its demands. The Act provides that "if the Local Government Board, under Section 101 of the Public Health (London) Act, are satisfied that the sanitary authority have been guilty of such default as is mentioned in such section, and have made an order limiting a time for the performance of the duty of the authority, the London County Council shall, if directed by the Local Government Board, withhold the whole or any part of the payment of the sum due to such authority" for the equalisation of rates.

Having thus obtained statutory control over the local distribution of funds, the London County Council will for the future have little difficulty in procuring the execution of all necessary works for the protection of the public health. After the manner of its predecessors, Mr. Shirley Murphy's report for 1895 treats in sufficient detail of the progress of local sanitary operations in aid of public health. It deals at length with such important topics as the prevention of trade and other nuisances, the housing of the working classes, the provision of workmen's trains, the regulation of houses let in lodgings, the supervision of the food and water-supply, and the maintenance of hospital and asylum accommodation for the treatment of the infectious sick and of the insane poor. All these subjects are dealt with so as to present under the respective headings a complete summary of existing sanitary conditions in the several sanitary areas. Opportunity is also taken to point out the general lines on which improvements can best be carried out, and copious extracts are appended from the reports of local medical officers of health, showing how far the suggestions of the central department have been attended to.

THE INTERNATIONAL SANITARY CONFERENCE.

OUR special correspondent writes:—The officially authorised report of the proceedings of the Conference will in due course be ready for distribution. It will be issued from Rome. In anticipation I may remark that its most outstanding feature will be the evidence it affords, as compared with its predecessors, of the steady progress made by British views of sanitation in Continental and even Eastern opinion. Difficulties as to their adoption may survive the recognition of their soundness, particularly with Powers like the Sublime Porte, which draws considerable revenue from "pilgrim dues" and other imposts of little or no real hygienic value. But as to the substantial victory scored by British prophylactic medicine, that may be regarded as *un fait accompli* on which civilisation may well congratulate itself.

With the signature of the "International Sanitary Convention" the Conference immediately rose.

Signor Bonin, the President, recapitulating its results, dwelt on the importance of the measures agreed upon as to the chief questions submitted to the Conference.

Thereafter the delegates of Austria-Hungary and France congratulated the Conference on its president, whose sympathetic tact had smoothed the many difficulties inherent in the discussions, and they concluded by begging him to convey to the Venetian public the gratitude of the delegates as a whole for the hospitality vouchsafed to them. The President, after returning thanks, declared the Conference closed.

Those who signed the Convention without reservations were the representatives of Austria-Hungary, Belgium, France, Great Britain, Italy, Luxemburg, Montenegro, the Netherlands, and Rumania.

The "Referendum" was signed by the representatives of Spain, Greece, Persia, Portugal, Servia, and Turkey.

The German representatives signed with reservations certain provisions to be adopted in Europe, as did also the representatives of Switzerland.

The representatives of Denmark, Sweden and Norway, and the United States accepted the Convention *ad*

Hosted by Google

referendum. They made a formal declaration, inserted in the *procès-verbal*, that their Governments, as far as possible, would apply the provisions established in the Convention before the term fixed for its ratification.

Germany, Austria-Hungary, France, Great Britain, Italy, Luxemburg, Montenegro, the Netherlands, Portugal, Russia, Roumania, and Switzerland, through the representatives of their respective Governments and administrations interested, will have yet to consider and decide upon the following arguments, viz. :—

1. Communication of the Sanitary Convention of Venice to the Sanitary Council of Tangiers in order that there may be taken at Morocco provisions conforming to the rules established by the Convention against the invasion of the pestis bubonica, especially with regard to the temporary inhibition or restriction of pilgrimages.

2. Unification of the prophylactic measures on the part of the authorities at Malta and Gibraltar conformably to the rules of the Venice Convention.

3. Coördination and codification within an approximate time of all the dispositions entered in the Conferences of Venice in 1892, of Dresden in 1893, of Paris in 1894, and of Venice in 1897 against cholera and the pestis bubonica.

To the Convention is appended a general sanitary regulation to prevent the invasion and the diffusion of the pestis. This consists of five clauses.

The regulation starts from the basis that the period of incubation of the disease is at the present stage of science ten days.

The first clause, besides general prescriptions as to the notification of cases of pestis and of the provisions taken, contains :—

1. Rules to be followed in infected ports regarding outgoing vessels and those to be observed during the voyage and at the ports of arrival. Special and most severe regulations are laid down for pilgrim ships, and pecuniary fines are imposed on captains contravening such regulations.

2. Rules to be followed with regard to the place of departure by land or sea from the infected countries and particularly by the Red Sea (Wells of Moses, Suez, passage of the Canal), with special consideration for the Mussulman pilgrims and in view of the sanitary reforms to be effected in the halting places where they are kept under surveillance (Camaran, Abousaad, Vasta, Abouali Gebel, Tor) and by way of the Persian Gulf.

The second clause contains rules to be observed in Europe and to establish reciprocal and continuous information between the Governments as to eventual cases of pestis, the provisions adopted to combat transmission, and the conditions under which the territorial circumscription ought to be considered sound or contaminated. It also determines the necessity of limiting the circumscriptions (province and department) contaminated, and the provisions for combating the invasion of the disease; it enumerates the goods and effects which may convey the germs of the pestis; it establishes provisions to be taken on the terrestrial frontiers, condemning once more the system of quarantine, and admitting as an exception the barring of frontiers. It determines, finally, the provisions to be taken in the zones of frontiers along river sides, canals, and at harbours.

The third clause contains, as a recommendation, instructions as to the method of disinfecting in presence or anticipation of the pestis.

The fourth clause indicates the provisions to be recommended on board ships at the moment of departure, during the voyage, and at the port of arrival.

The fifth clause determines the mode in which surveillance is to be exercised in terms of the rules and provisions proposed by the Sanitary Council of Constantinople, with regard to the Red Sea, the Persian Gulf, at the Turko-Russian and Turko-Persian frontiers, and by the Sanitary Council of Egypt for maritime quarantine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia of the Royal College of Physicians was held on March 29th, the President, Dr. WILKS, being in the chair. Communications were read from (1) the Secretary of the Royal College of Surgeons of England reporting the proceedings of the Council; (2) the General Medical Council forwarding a report from the Medical Department of the Navy pointing out that three Licentiates of the College at a recent competition showed deficiency in preliminary education; (3) Dr. H. G. Adamson, resigning his membership and returning his diploma; and (4) the Sanitary Institute, inviting the College to send two delegates to the annual congress to be held in Leeds in September next. It was resolved that Dr. Barrs and Dr. Chadwick be invited to act in that capacity.

A communication was read from the Medico-Chirurgical Society of Norwich enclosing a resolution of the society with reference to the medical officers of medical institutes. This was in the form of a memorial to the College, pointing out the urgent necessity of steps being taken in this matter, and stating that the members of the society have declined professional intercourse with those who by accepting offices in such associations had taken on duties derogatory to the profession.—The Beckenham Medical Society also forwarded a resolution declaring the holding of such appointments to be inimical to the best interests of the profession.

The PRESIDENT then submitted to the College the report of the committee appointed on February 23rd of this year to advise the Royal College of Physicians of London on the desirability of making a formal declaration of opinion to the Government in favour of the re-enactment of the Contagious Diseases Acts, or some such modifications of them as may prevent the spread of these contagious diseases.

After referring to the lamentable increase in recent years in the number of soldiers invalided home from India suffering from syphilis, and to the statistical aspect of the matter as revealed in the recent report of the Departmental Committee of the India Office, the committee of the College went on to say that whether syphilis be regarded in relation to the large amount of inefficiency it causes in the British Army and consequent weakening of the military power at the disposal of the Government of India, to its present, and often life-long, effect on the health and constitutions of the individual sufferers and their future wives and children, or in relation to its remoter consequences on the well-being of future generations, it appeared to them to be a matter of serious moment and to call for the gravest consideration. From this last fact it followed that if all reasonable measures to limit the spread of infection were justifiably taken in the case of other contagious or infectious diseases, they were far more necessary in the case of syphilis. About 13,000 soldiers return to England from India every year, and of these in 1894 over 60 per cent. had suffered from some form of venereal disease. These figures were quoted as showing more forcibly than words the risk of contamination to the present population and to future generations.

The report concluded as follows :—

"The far-reaching effects of syphilis are so serious that it is of the first importance that the earliest indications of the disease should be medically treated without any loss of time; neglect of this measure tends to increase its virulence in all its stages.

"As regards the unfortunate women who pursue their calling in a diseased condition, it is simply a matter of humanity to them that they should have the benefit of medical treatment, with rest and care in hospital, until they are cured.

"In view of this lamentable prevalence of disease your committee makes the following

Recommendations and Suggestions :—

That as the civil, military, and medical officers in India are best acquainted with the local conditions now existing, and affecting this prevalence of venereal disease, so they are the best judges of the most efficient means of dealing with it. Your committee therefore suggests that power be given to the Government of India to take such steps for the mitigation of this evil as these officers may advise.

That, for the protection of the healthy population, venereal diseases in both sexes, in the soldiers as well as the women, be subjected to the same restrictions as are other contagious diseases, such restrictions having for their object the detection and prevention of such diseases.

With regard to the unfortunate women, such measures necessarily include examination as well as treatment; and it may be desirable in India that the examination should be performed by persons of their own sex, who have been sufficiently trained and educated for the efficient discharge of this duty.

Syphilis requires prolonged constitutional treatment, during which the sufferers should be under frequent medical supervision, although not necessarily hospital *in*-patients.

Your committee also suggests that no women should be employed as coolies in, or in the immediate vicinity of, the barracks, as there is evidence that such women are frequently the source of aggravated forms of venereal disease.

"In making these recommendations your committee considers that they should apply not only to the women, but also to the men with whom they consort; and is of opinion that it would be highly advantageous if medical officers in the army found some means, by elementary reading-room lectures or otherwise, of acquainting young

Hosted by Google

and inexperienced soldiers with the grave and far-reaching consequences that are likely to result from immoral conduct, as well as from the concealment of the primary symptoms of the disease, the early treatment of which is of the utmost importance."

Dr. CHURCH (Senior Censor) moved the adoption of the report, and Sir DYCE DUCKWORTH seconded the motion, remarking that it was the business of the medical profession to lead in this matter.—Sir JOSEPH FAYRER urged the necessity of the authorities taking disciplinary measures as well as medical and sanitary precautions, for there was absolutely no reason why these diseases should be so rife in India if proper control were exercised.—Sir W. PRIESTLEY, Dr. PLAYFAIR, and Dr. CHURCH also spoke, the latter mentioning the fact that the trained medical women in India consisted of three classes—the lady doctors, the assistant surgeons, and the hospital assistants, and there was reason to believe that these were sufficiently numerous to undertake the duties suggested to be imposed on them, of course under supervision. The report was adopted by the unanimous vote of the College.

A report from the Council dealing with the memorial addressed to the College at its last meeting by medical practitioners of Norwich was, after some debate, referred back for further consideration.

A report from the Midwives Registration Bill Committee was received and adopted.

Reports were received and adopted from the Committee of Management and the Laboratories Committee.

BUBONIC PLAGUE IN BOMBAY.

IT is reassuring to learn from the Anglo-Indian papers received by the last mail, although the news has been anticipated by telegraphic intelligence, that things have taken a favourable turn and are progressing more satisfactorily. The *Times of India* of March 13th, which publishes full accounts of all the proceedings that are taking place in Bombay in reference to the epidemic, states that there was a considerable diminution in the Bombay mortality returns during the past as compared with the preceding week, the numbers being 1326 and 1484 respectively, and the number of deaths registered from plague had fallen to 590. The health of the city was, in fact, showing considerable signs of improvement and business was beginning to revive.

At Karachi and Poona, on the other hand, where the epidemic was still spreading, drastic measures were being adopted for its suppression. The powers conferred by the Epidemic Diseases Act of 1897 are very considerable and go straight to the point, and the Executive Committee are energetically carrying out, under the orders of Government, measures for the suppression or limitation of the spread of the disease. It has been notified in the *Bombay Gazette Extraordinary* that the Municipal Corporation of the City of Bombay, its officers and servants, and all public servants are to give effect without delay to any measures that may be ordered by the committee, who have also power to requisition the Commissioner of Police to afford such aid as may be necessary to enforce them. Provision is likewise made for the expenses incurred in carrying out these measures. Dr. Yersin, accompanied by M. Pilinsky, the Consul, and Comte de Potier, the Vice-Consul, for France, arrived at Bombay from Poona on the 5th ult., the former bringing with him a large supply (700 tubes) of anti-plague serum, prepared in his laboratory at Nha-Trang, in Annam. Dr. Yersin has set to work very energetically, but it will be seen from the substance of a telegram which we publish in another column that his results in India do not appear to be so successful as those he obtained in China. Meanwhile we glean from the *Times of India* some particulars which may prove of interest to our readers. The Executive Committee in Bombay, under the presidency of General Gatacre, have circulated a note to district medical officers briefly setting forth that Dr. Yersin has been sent by the Institut Pasteur at Paris to repeat on a larger scale the successful experiments previously carried out by him in China; that the inoculations will be conducted free of charge; and that Dr. Yersin puts himself at the disposal of the municipality of Bombay and the public in order that those who desire to do so may try his treatment.

Reference is made to the volumes of the *Annales de l'Institut Pasteur*, which deal with Dr. Yersin's researches regarding plague and the technical preparation of the serum employed by him. The circular note goes on to state that Dr. Yersin has for his aim: 1. To treat with his serum declared cases of plague in order to demonstrate the efficiency of the new medicine. It is necessary for the success of the treatment that the disease should be treated at its commencement. The longer the disease has lasted the more difficult it is to deal with. However, in any case the treatment is innocuous. 2. In houses where plague exists Dr. Yersin can inoculate those who are inclined to try the influence of the preventive serum; he will also inoculate native practitioners and their staffs or any European medical practitioners who apply to him. The injection of the serum is not more painful than a subcutaneous injection of pure water; it causes no uneasiness, fever, or abscess. The patients have not to follow any special treatment or diet. The length of the immunisation acquired by the injection of serum is about a month; after the lapse of this time a fresh injection should be applied for, with the object of renewing the period of immunisation. The serum prepared by Dr. Yersin does not contain any microbe or any poisonous substance; it is therefore absolutely harmless.

M. Haffkine's scientific labours in the same or a similar direction are well known, and he has been indefatigable in his efforts. The work of inspection, systematic and effective segregation, and sanitation is being pushed on steadily in all directions, not only in Bombay, but in Poona, Karachi, and other places. While the more intelligent and educated classes in India — whether Hindus, Mohammedans, or Parsees—have most creditably been doing their best to aid in the good work, it cannot be expected that the natives generally would overcome their fears and caste prejudices and not seek to escape from or evade the regulations by the concealment of their disease; that is quite natural, and such as we know takes place in other countries than India. Still, it is surprising how the natives, of that country are becoming amenable to reason in these respects and conforming to regulations the benefit of which they are gradually recognising. The *Times* correspondent says: "The ignorance and superstition of the lower class of travellers makes the work of the medical officers difficult. One belief is that persons removed to the segregation sheds are given medicines which put an end to them quietly. Hence there are attempts to evade inspection, passengers alighting at roadside stations and journeying on foot past the junctions where the examination is made. The outbreak, which occurred at a village in the Gwalior territory, only ten miles from Jhansi, may be traced to this practice. For six weeks the villagers maintained secrecy about the disease, losing over 50 persons out of a population below 300. When the outbreak was discovered the Gwalior Durbar sent Dr. Crofts, who placed a cordon round the village, removed the inhabitants to a camp, and burnt all the houses there. These measures proved most effectual, only six patients now remaining. A careful examination of the neighbouring villages shows that no single case of plague has occurred there. The epidemic is practically stamped out. The Bengal Government has issued a notification containing rules for dealing with the plague on its first outbreak. In country towns and villages the main principle is the prompt segregation of patients and destruction of infected material. Similar measures are being taken in other provinces. There is no plague in the Bengal Presidency, but these precautionary measures are deemed advisable."

The report that plague had attacked the British troops at Colaba is officially contradicted.

THE BATTLE OF THE CLUBS.

ACCRINGTON.

THERE is—or perhaps we ought to say was, for apparently it has ceased to exist—a "club" at Accrington called the Accrington Medical Dispensary. The club employed a medical officer and seems to have been conducted in a very remarkable and high-handed manner. As far as we can judge from the report of a meeting published in the *Accrington Observer* of March 6th—a very undignified and quarrelsome meeting apparently—the committee or trustees, or, at any rate, the governing body of the club, discharged the medical officer, handed over the care of the members

Hosted by Google

to the Accrington Medical Society, and sold up the fittings of the surgery and the drugs. We are not surprised; but as we gather from a remark of one of the speakers at the meeting that an action is pending between the medical man and the trustees of the dispensary we shall offer no comments at present. Meanwhile, the Registrar of Friendly Societies has been called in to inquire into the whole matter.

THE WIGAN AND DISTRICT MEDICAL GUILD.

The first annual general meeting of this guild was held on March 11th, Mr. J. B. Stuart being in the chair. The honorary secretary in explaining the movement said that their motto was at present "Defence, not defiance." Such an organisation was absolutely necessary in the interests of the profession. It was practically trades unionism applied to the medical profession. What was now wanted was organisation, not fighting. The reassuring effect of a powerful organisation was needed. He strongly disapproved of little individual fights being waged up and down the country, which by their want of success were apt to frighten the medical men in other districts. It might be magnificent but it was not scientific, warfare. It would be an extraordinary thing if a learned profession could not apply to its own necessity the old fable of the bundle of sticks. It would be observed that the rules adopted were practically the same as those of the Manchester Medical Guild. The cause of this was a strong desire that the two guilds should keep closely in touch. He hoped to shortly see similar guilds springing up in all the chief centres of Lancashire, so that a county federation might be formed. He would be only too happy to give all information to those desirous of helping forward the movement.

We are glad to see that Lancashire is aiming at the ideal of coöperation in medical defence. It was undoubtedly much more pleasant for everyone when the personal element could enter into the relations between employer and employed, as in the old days when apprentices lived in their master's house and the employer himself lived over his shop and was not ashamed to call it a shop. Nowadays he calls it an emporium and as a rule knows nothing of his "hands," though to this rule there are noble exceptions. So it is with medical practice. The modern club medical officer is ground down to give his services for a starvation wage, and has no Factory Acts or "unions" to defend him against what is sometimes the very real tyranny of his employers. So he is learning by bitter experience, and he is adopting the methods of his employers—i.e., patients—and, though we fear he will never get an eight hours' day, he will at least attain to "a fair day's wage for a fair day's work." The rules of the Manchester Guild referred to by the secretary of the Wigan society are mainly as follows:—

That the rate of payment should never be less than 4*s.* per member per annum; that the duties of medical officers should be clearly defined and uniform; that a rate of 2*s.* 6*d.* should be charged for the medical examination of every candidate; that a club medical officer should not be debarred from obtaining the usual fees under the Employers' Liability Act and the Lunacy Act; and that women should pay 6*s* a year. The Council of the Guild also consider that the profession should only recognise those provident associations which enforce a wage limit and which allow no laymen to make profits or accumulate reserve funds out of medical work, or medical men to be controlled by other than medical committees; and, also, that no medical officer should undertake to attend and dispense medicine for more than 1500 patients living within a radius of two miles.

We earnestly hope that the suggestion of the Wigan secretary will be acted upon and a county federation formed, for such an association would be of incalculable value to practitioners of all grades.

After the meeting the following officers were elected:—Chairman: Mr. W. Mitchell Roocroft. Vice-chairman: Mr. C. R. Graham. Honorary secretary: Dr. F. Rees. Honorary treasurer: Dr. M. Benson. Council: Mr. Cooke, Mr. Parker, Dr. Wilson, Mr. Cbronnell, Dr. Wolstenholme, Mr. Berry, Mr. Monks, Mr. Brady, Mr. Angior, Mr. Cowan, Dr. Blair, and Dr. J. King.

MEDICAL MEN AND FRIENDLY SOCIETIES.

On March 19th the annual Conference of the Affiliated Friendly Societies of the United Kingdom was held in London, when the question of "medical boycotting," as the determination of medical men not to be robbed was gracefully termed, was discussed. Mr. Lister Stead, of the Ancient Order of Foresters, proposed the following resolution, we learn from the *Sheffield Independent* of March 20th:—

"That this Conference of Friendly Societies records its strong protest against the organised attempts made by medical men to impair the usefulness of the medical aid section of the work of friendly societies, especially to the boycotting directed against medical men in the service of Friendly Societies' Medical Institutes or Associations, and in regard to the restrictions sought to be imposed by medical men as to the class of persons eligible to receive medical benefits through friendly societies; and this Conference instructs its committee to take steps to protect the interests of the societies concerned, and to uphold the right of the societies to admit members free from any restrictions on the part of the medical profession. That copies of this resolution be forwarded to the Medical Council and the editors of THE LANCET and *British Medical Journal*."

According to the *Sheffield Independent* Mr. Stead went on to say that those interested in these matters were beginning to recognise that throughout the United Kingdom efforts were being made to hamper the work of the societies as regarded their medical aid branches. The medical men were now combining to make it as hot as possible for the gentlemen who acted for the Medical Aid Association. His society thought that if the Conference expressed an opinion upon this practice of boycotting it might have the effect of putting a stop to this practice, or, at all events, of mitigating the evils under which they were labouring to-day. As to the attempt of the medical profession to impose a wage limit for members, they would not allow the medical profession to lay down rules under which they should admit members.

We believe that Mr. Stead's resolution was adopted, though it has not been forwarded to us in accordance with its wording. We are glad to learn that Mr. Stead's friends are beginning to find out that the medical profession does not intend to be exploited, and we assure him that no resolutions that he can frame will "have the effect of putting a stop" to action on the part of medical men against organised robbery. We beg again to repeat to the medical profession that on no account should they accept office in clubs where there is no wage limit and where the patients of other medical men are touted for by canvassing.

BECKENHAM AND PENGE MEDICAL SOCIETY AND THE CLUB QUESTION.

At a meeting of the above society, held on March 12th, the following resolution was proposed and unanimously carried:—

"That it is detrimental to the honour of the medical profession that a member should hold any appointment under medical aid societies, because they are speculating companies, increasing their profits by imposing on the medical profession, to whom their success is largely due. This society therefore protests, and pledges itself not to take any such appointment, and it is their earnest hope that their professional brethren will do likewise and so suppress these impositions, which, if encouraged and allowed to continue, must seriously injure the *bonâ-fide* work of the general practitioner amongst the middle and lower classes."

THE RECORDS OF FATALITIES UNDER ANÆSTHETICS.

AMONG the sad deaths under anæsthetics, which nowadays seem so frequent, many are placed to the account of anæsthetic agents without any justice. In pre-anæsthetic days it was no uncommon occurrence for death to take place before the surgeon's knife had commenced its work, nor was it rare for a fatal swoon to terminate abruptly the performance of an operation. The enormous increase in the actual number of times an anæsthetic is given now as compared with ten years ago involves a far larger number of actual deaths, although the same low average of mortality is maintained or even lessened. It is certainly true that there is much to be learned from fatalities; and, although always sad reading, we must submit that no death which occurs under an anæsthetic should be passed over, but carefully noted and published, that it may prove a beacon which may perhaps save others from some unappreciated shoal or rock in the troubled waters of anæsthesia. And in this connexion we would remark that when details are sought for the narratives sometimes fall short. We are told that chloroform was given "in the usual way," regardless of the fact that the usual way for A. is not the method adopted by B. A brief newspaper cutting is sent with the remark "correct as far as it goes." The *petitio principii* is here evident, for what we

Hosted by Google

need is not the *parvum in multo* but the *multum in parvo*. If our correspondents would critically examine whatever account they send us and give all information in their power about the patient, the anæsthetic, the method of anæsthetising, and the phenomena of anæsthesia, they would do much to assist others—and perhaps render a service to themselves—by a searching examination of the side lights thus thrown upon the occurrence.

DEATHS UNDER CHLOROFORM IN DENTAL OPERATIONS.

We have received from the chloroformist the particulars of the following death under chloroform. The patient, a woman, aged twenty-five years, was in good health and of spare habit. The clothes were loosened, while the patient reclined upon a couch with a view to having several teeth extracted under chloroform. The anæsthetic was administered from a felt cone, a drop-bottle being used. In about five minutes the conjunctival reflex had disappeared. After most of the teeth had been removed the dentist changed the gag to the other side of the mouth. At this time the patient appeared to be doing well. The pupils were moderately contracted. More teeth were removed, with, as we gathered, occasional re-applications of the cone. When this was lifted off the face for the last time the colour appeared to be natural, but the chloroformist says that he could not see the chest. When the last tooth was removed the lips were seen to be pallid and respiratory movements had ceased. Careful measures to effect resuscitation failed. The necropsy revealed that the right heart was empty, and the left full; all other organs were normal. Two drachms of chloroform were used. That anæsthetic was only selected in place of ether at the last moment, but why this change was made we are not informed.

A similar occurrence is reported. In this case the patient (again a female) was aged thirty-two years; the administrator was a surgeon and the family attendant of the patient. Chloroform was given from lint. The patient succumbed as the operation was finished; respiration was observed to fail. The necropsy showed a distended stomach and "weak heart"—whatever that may signify. It would be interesting to know why chloroform was employed in these cases, as experience has shown that fatalities are peculiarly liable to follow the use of chloroform in dental operations. That shock is peculiarly prone to take effect in such cases is generally believed, but it is more likely that in the chloroformist's desire to ensure a prolonged and complete anæsthesia the anæsthetic is usually pushed to a dangerous degree. Commonly the very act of removing teeth causes obstruction to respiration, either from pushing back of the tongue or pressure upon the mandible. Whether death results from an excessive or an insufficient quantity of chloroform really matters very little, but what is of the last importance is that death be avoided by giving the patient nitrous oxide gas on several occasions or, if this is impossible, by having recourse to a full anæsthesia by means of nitrous oxide and ether. It should be noted that in the cases given above in one instance a closed cone and in the other lint was used. A death under nitrous oxide and ether has been recently reported, but at present we have not received sufficient information to enable us to do more than notice this unusual and deplorable mishap.

DEATHS UNDER ANÆSTHETICS IN OTHER OPERATIONS.

A death occurred in Liverpool under chloroform. The patient, aged twenty-two years, an inmate of the workhouse infirmary, was placed under chloroform, and before the operation was commenced his condition became so grave that the administration was stopped and artificial respiration commenced. This brought him round. The anæsthetic was again given, and this time the patient died. The necropsy seems to have shown old pericardial adhesions. It would be interesting to know why the administrator did not change the anæsthetic if the urgency of the case was such as to render it desirable to complete the operation on the day.

Through the courtesy of the house surgeon, Mr. S. T. Rowling, M.B., Ch.B. Viet., we have before us the particulars of a death under A.C.E. mixture which took place at the Leeds Infirmary. The patient suffered from right-sided empyema and had been an in-patient for a month, having been twice aspirated without anæsthetics being employed. On the day of his death A.C.E. mixture was given him, how we are not informed, and after six and a half drachms had been used he died "from syncope." The breathing stopped quite suddenly before the operation was commenced.

Another case of death during the performance of an operation for empyema is reported by Mr. W. J. Scott, to whom we are indebted for careful notes. The patient, an alcoholic man, aged forty-five years, came under treatment for left-sided empyema. Large quantities of fœtid sputa were being expectorated. He was unable to lie in the dorsal decubitus owing to dyspnœa. The administration of the anæsthetic was was commenced by giving A.C.E. mixture from a Skinner's mask held at a little distance from the patient's face. In about one and a half minutes this was replaced by ether given with extreme caution from a sponge in an open celluloid cone with abundance of air. After four minutes slight rigidity was present, but the conjunctival reflex and cough persisted. The pulse and colour were both good, and when some slight stertor was heard it was decided to commence the operation, although the conjunctival reflex was not abolished. The patient was turned on his sound side, and before the parietes could be incised down to the bone the patient grew cyanosed and breathing was embarrassed. The anæsthetic was stopped as soon as the change in posture was effected. Upon the onset of these grave symptoms the patient was turned on his back, the jaw held forward, and slight pressure made upon the ribs of the sound side, the shoulder and arms being extended in inspiration. The breathing then grew regular and the pulse became fairly good. The patient was then placed at the edge of the table and turned slightly on his sound side. The cyanosis at once re-appeared and quantities of fœtid pus poured from the mouth. Artificial respiration only appeared to increase this condition, and the patient died. We can only deplore with Mr. Scott the result of the case. The notes show that everything which human foresight could indicate was done, and that the unhappy patient's condition rendered it practically a foregone conclusion that even the greatest skill and care must fail to obviate a fatal issue.

In the next case the patient seems to have been in a grave condition due to peritonitis following intestinal obstruction, and upon being taken to the infirmary at Stafford, where he was given chloroform, it was found that his condition grew worse under this anæsthetic, so that a mixture of it with ether was substituted. Under this, however, he sank and died. It is probable that here the anæsthetic only accelerated the death, and we may perhaps assume that the most depressing form of anæsthetic was at first used for reasons which do not appear in the account of the fatality which lies before us. In many such cases a very small amount of an anæsthetic—ether for choice, as it stimulates—suffices for incision of the abdominal parietes, and the subsequent procedure can be carried through with practically no further anæsthetic. A whiff at the close of the operation when skin sutures are being applied will render the procedure painless.

THE HEALTH OF THE EUROPEAN ARMY IN INDIA.

THE Army Health Protection Association, India, has issued a memorandum setting forth the history of the political and other changes affecting the health conditions of the troops composing the European force in India, and the causes which in their opinion have given rise to the great prevalence of contagious diseases existing at the present time. A letter, signed by Colonel F. C. Keyser, the honorary secretary of the association, accompanies the memorandum, in which the increase of disease is attributed to the partial, and at last complete, abandonment of measures of control and protection in cantonments. After succinctly referring to the successive steps taken in this policy of abandonment forced upon the Government of India, the letter goes on to state that the objects of the association are twofold—to furnish the public with a correct account of the facts of the case and clear away the ignorance and misunderstanding which at present beset the subject; and to bring to bear on the Government the force of a combined, rational, and well informed public opinion. The memorandum discusses the subject more in detail, and should be studied by all who are interested in the question. There is no need for us to express our concurrence in the objects of the association, for readers of THE LANCET must be thoroughly aware of the views entertained by us in regard to the subject in question.

A NATIONAL MEMORIAL TO JENNER.

A MEETING was held on Wednesday last, March 31st, in the theatre of the University of London, with the object of establishing a national memorial to Edward Jenner. The Duke of Westminster, K.G., presided. Among those present were the Duchess of Westminster, Lord Herschell, G.C.B. (chairman of the Royal Commission on Vaccination), Lord Lister (President of the Royal Society), the Earl of Cork and Orrery, K.P., Professor Michael Foster (Secretary of the Royal Society), Sir Alfred Lyall, K.C.B., Lord Davey, Mr. Brudenell Carter, the Earl of Ducie, Viscount Clifden, Dr. S. M. Copeman, Sir H. Cunningham, Sir John Evans, Dr. W. Ewart, Sir Joseph Fayrer, Sir W. H. Flower, Dr. Glover, Dr. John W. Ogle, Sir H. Roscoe, and Colonel Keyser, C.B.

In opening the proceedings the DUKE of WESTMINSTER said he was the nephew of one who at the commencement of the century contracted the disease of small-pox ten years after he had been vaccinated by Jenner himself—quoted as a proof of the failure of the system—but who, if a failure, was none the worse for the attack, and lived without spot or blemish through the greater part of this century, leaving us only a few years ago at the good old age of ninety-two. The present meeting was the outcome of a preliminary gathering held in December of last year, on which occasion, while there was a remarkable unanimity on the part of gentlemen of eminence and authority attending it, some little doubt was expressed by one or two who were present as to whether it would be advisable or prudent to attempt to connect the memorial with any particular institution. That doubt was, however, not crystallised into any shape or form of opposition and he took it that an overwhelming conviction obtained in the minds of all sensible people that the world owed a deep debt of gratitude to Jenner for saving its inhabitants from a foul disease if only they would adopt his treatment carefully and periodically. He referred to the false and misleading statements that were circulated among the ignorant, prejudicing their minds against vaccination, which had told so disastrously in Jenner's own county at Gloucester, where it required a severe epidemic of small-pox to convert the anti-vaccinationists there into fervent admirers and adopters of vaccination. It was surely high time that this, the native land of Jenner, should rise to the occasion and, after 100 years after the first successful vaccination, take active and effective steps to carefully preserve his great legacy to the world, and to do more, to give every facility for the promotion of science in the direction of the prevention of diseases. It had been suggested that the statue of Jenner now in Kensington-gardens, a site hardly worthy of him, might be removed and placed opposite St. George's Hospital, but he ventured to think that his native village of Berkeley might perhaps more fittingly receive it.

Lord HERSCHELL, in moving the first resolution, "That the present is an appropriate time to inaugurate a work of national utility in honour of Edward Jenner," said a hundred years ago small-pox was committing ravages which we could now hardly realise. Jenner introduced to the world his discovery that inoculation of cow-pox would prevent attacks of the disease, and at the end of the first quarter of the century a marked change was seen not only in this country, but in many of the countries of Europe. From the outset there had been those who doubted the efficacy of vaccination, and the Commission on the subject, over which he presided for many years, had just issued its report. A vast amount of material was considered, and it fell to his lot to have to digest that material, analyse it, and submit a report for the consideration of his colleagues. When he approached that task he approached it with a determination to follow the results to which the facts led whatever they might be, and he was surprised at the force of the evidence in favour of vaccination. From the Blue-book he quoted figures in favour of vaccination which, he said, it was difficult for human reason to resist. Jenner's character and veracity had been attacked by some peopul who pointed out that he asserted or expected that vaccination would be permanent in its effects, while everybody now admitted that absolute permanency did not exist. The only way to tell whether it would be permanent or not was by experience, and those who availed themselves of the experience of a century of vaccination to assail Jenner, who necessarily did not possess that experience, were the same persons who very often refused to yield to the teachings of experience when they inquired now what had been the effects of vaccination. Jenner was the first to illustrate a principle which seemed destined to play an important part in the history of preventive medicine. Surely this alone was a high tribute to Jenner and the value of his discovery. His name was held in reverence by the highest men of science and the most civilised countries in the world. Some of those countries had commemorated his centenary. Jenner was an Englishman, and were Englishmen to be behindhand in testifying their admiration of the man and their sense of the benefits he had conferred on humanity?

Professor MICHAEL FOSTER, who seconded the resolution, said he would like to re-echo the words of Lord Herschell and claim for Jenner's work scientific merit. Except, perhaps, for the fact that the labours of Dr. Monckton Copeman and others tended to minimise the dangers of vaccination, relatively little progress had been made in the principles laid down by Jenner till the time of Pasteur. Jenner was governed by the idea we now call the doctrine of attenuation, a doctrine revived by Pasteur, and which had become the basis of our great progress at the present time.

Sir ALFRED LYALL supported the resolution, which was carried unanimously.

Lord LISTER moved: "That a subscription be set on foot with a view of promoting, in connexion with the British Institute of Preventive Medicine, but in a manner distinguished by Jenner's name, researches on the lines which he initiated." In proposing the resolution Lord Lister took occasion to correct a mistake which he made in his presidential address to the British Association at Liverpool. The mistake, he said, had been made a very great deal of in the newspapers and had been taken advantage of by the anti-vaccination party in distributing a leaflet to that meeting. The statement was to the effect that small-pox was absolutely unknown in the German army as a result of the re-vaccination of all recruits. He had quoted from memory after reading an authority on the subject, and if he had stated that "fatal" small-pox was absolutely unknown in the German army he should have been speaking the literal truth. Such being the case, he did not think it necessary to rectify in a public manner the mistake he had made when a letter appeared in the *Times* of Sept. 23rd of last year calling attention to this mistake. He had since obtained the official documents from which the writer of this letter had taken the facts to convict him. Now he asserted that from 1874–75 to 1886–87 the only death from small-pox that occurred in the German army was that of a man who was proved not to have been properly vaccinated. If, instead of deaths, he took the cases, in 1886–87 there were seven out of 344,000 men, in 1885–86 there were six, in 1884–85 there were seven, and so on. He thought, therefore, he had not made any very serious blunder after all. The writer of the letter had also contended that vaccination had had no influence whatever in diminishing the death-rate from small-pox in the German army. He (the speaker) had examined the official statistics, and found that from 1874–75, when the Compulsory Re-vaccination Law was passed, the mortality from that cause in the army had become absolutely *nil*. Not only so, but, as a German authority himself had been lately saying, Germany might now be said to be practically free from small-pox. He was glad to take this opportunity of correcting his mistake, because it enabled him to support the principle of vaccination from German statistics He pointed out the value of research on the lines laid down by Jenner, giving as examples Dr. Koch's treatment of rinderpest in South Africa, M. Haffkine's inoculations in connexion with the bubonic plague, the experiments of Dr. Yersin, and the results obtained by the use of anti-diphtheric serum in this country, which had saved a multitude of young lives, and which was due to the Institute of Preventive Medicine. He suggested that this name might possibly be altered to that of the Jenner Institute.

Lord DAVEY seconded, and Mr. BRUDENELL CARTER supported, the resolution, which was carried unanimously.

A vote of thanks to the chairman, proposed by the Earl of DUCIE and seconded by Dr. GLOVER, terminated the proceedings.

VENEREAL DISEASE AMONG THE INDIAN TROOPS: THE ACTION OF THE GOVERNMENT.

A MILITARY despatch from Lord George Hamilton to the Government of India, dated March 26th, 1897, was presented to the House of Commons on Thursday, April 1st. After recapitulating the facts and figures proving the terrible increase in venereal ravages among the Indian troops Lord George Hamilton goes on to say:—

"Your Excellency will, I am confident, concur with Her Majesty's Government that in any measures which may be adopted there must be nothing that can be represented as an encouragement of vice. There must be no provision of women for the use of soldiers by any authority, civil or military. There must be no registration of prostitutes other than that which is, or should be, enforced for all inhabitants of cantonments, and no granting of licences to practise prostitution. There must be no compulsory and periodical examination of women. Prostitutes must not be allowed to reside in regimental bazaars or to accompany regiments on the march. Subject to these restrictions, Her Majesty's Government consider that Rules 5, 6, and 7 of the Cantonment Rules[1] made in 1895, under Sections 26 and 27 of the Cantonment Act of 1889, should be made applicable not merely to 'cholera, small-pox, diphtheria, or typhoid fever,' as specified in the rules, but to all contagious and infectious diseases, including venereal disease. They consider it imperatively necessary that this disease should not be exempted from the measures adopted to prevent the spread of other contagious diseases. It may be argued that the examination of women which may, but need not necessarily, be held under these rules is in effect compulsory. Her Majesty's Government do not share this view. But if there be any compulsion it is precisely of the same kind as that which has been accepted as necessary and enforced without any objection in the case of diphtheria or typhoid fever. There will be no obligation on women to attend hospital, but as an alternative to doing so they will be required to leave the cantonment, and rightly so, as an almost certain cause of disease to others. Her Majesty's Government also approve of the suggestion made by the Army Sanitary Committee as to the employment of female hospital assistants under the direction of the medical officer in the examination and treatment of women."

It is to be hoped that these measures will mitigate the terrible scourge, but we await, before expressing any opinion on the point, the draft rules that the Indian Government will now issue to give effect to the despatch. On these everything will turn.

[1] The following are the clauses from the Cantonment Rules:—"5. If the medical officer for the time being in charge of any such hospital is informed upon testimony which he believes to be credible that any person living in the cantonment is suffering from cholera, small-pox, diphtheria, or typhoid fever, he may by notice require such person to attend at the hospital at a time to be mentioned in such notice; and if upon the attendance of such person in pursuance of such notice or otherwise he shall ascertain that such person is in fact suffering from any of the above-mentioned disorders, he may require such person to remain in the hospital until he shall have been pronounced free from such disorder, or may give such other direction in the matter as may seem to him most expedient for the purpose of preventing the spread of such disorder. 6. If any person upon whom any such notice as is mentioned in the last preceding rule shall have been served shall refuse or neglect to attend at the hospital in pursuance of such notice, he shall be deemed to be suffering from such disorder as aforesaid and to have refused to go to the hospital. 7. If the medical officer for the time being in charge of any such hospital certifies in writing to the commanding officer of the cantonment that any person living in the cantonment is or is deemed to be suffering from any of the disorders mentioned in Rule 5, and that such person has refused or is deemed to have refused to go to the hospital, or that he, having gone to the hospital, has left it while still under the influence of such disorder, and that the continuance of such person in the cantonment is likely to be attended with danger to the health of the other inhabitants of the cantonment or some of them, the cantonment magistrate may, on the application of such medical officer, order such person to remove from the cantonment within twenty-four hours, and prohibit such person from remaining in or re-entering it without the written permission of such meaical officer."

A COMMISSION has been signed by the Lord-Lieutenant of the County of London appointing as a Deputy-Lieutenant of the County Mr. Frederic Hetley, M.D. St. And., F.R.C.S. Eng., of Norbury Lodge, S.E.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6697 births and 3939 deaths were registered during the week ending March 27th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 18·1 to 18·7 per 1000, was again 18·7 last week. In London the rate was 17·9 per 1000, while it averaged 19·2 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·9 in Croydon, 13·2 in Bristol 13·6 in Derby, and 13·7 in Brighton; the highest rates were 22·3 in Bolton, 23·2 in Norwich, 24·0 in Nottingham and in Manchester, and 24·2 in Salford. The 3939 deaths in these towns included 360 which were referred to the principal zymotic diseases, against 335 and 344 in the two preceding weeks; of these, 98 resulted from whooping-cough, 88 from measles, 64 from diphtheria, 43 from diarrhœa, 37 from scarlet fever, and 30 from "fever" (principally enteric). No fatal case of any of these diseases was recorded last week either in Wolverhampton, Derby, Birkenhead, or Halifax; among the other towns they caused the highest death-rates in Birmingham, Blackburn, Burnley, Salford, and Bolton. The greatest mortality from measles occurred in Cardiff, Bolton, Salford, and Burnley; and from whooping-cough in Swansea, Burnley, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 64 deaths from diphtheria included 43 in London and 3 in Birmingham. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 21 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 27th, against 30, 29, and 21 at the end of the three preceding weeks; 2 new cases were admitted during the week, against 6, 0, and 2 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2585, against 2745, 2685, and 2622 on the three preceding Saturdays; 224 new cases were admitted during the week, against 211, 218, and 206 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 344 and 317 in the two preceding weeks, further declined to 313 last week, and were 164 below the average. The causes of 51, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Bradford, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Preston, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·1 and 23·3 per 1000 in the two preceding weeks, declined again to 22·6 during the week ending March 27th, but exceeded by 3·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·1 in Greenock, and 16·8 in Paisley, to 26·3 in Aberdeen, and 30·7 in Perth. The 673 deaths in these towns included 36 which were referred to measles, 33 to whooping-cough, 16 to diarrhœa, 4 to scarlet fever, 4 to "fever" and 3 to diphtheria. In all, 96 deaths resulted from these principal zymotic diseases, against 83 and 106 in the two preceding weeks. These 96 deaths were equal to an annual rate of 3·2 per 1000, which was 1·5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 27 and 33 in the two preceding weeks, further rose to 36 last week, of which 19 occurred in Glasgow and 16 in Edinburgh. The 33 deaths referred to whooping-cough corresponded with the number recorded in the preceding week, and included 22 in Glasgow and 9 in Edinburgh. The fatal cases of scarlet fever, which had been 5 and 9 in the two preceding weeks, declined again to 4 last week, of which 3 occurred in Glasgow. The deaths referred to different forms of "fever," which had been 4 and 11 in the two preceding weeks, fell to 4 last week, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 152 and 155 in the two

Hosted by Google

preceding weeks, further rose to 159 last week, and exceeded by 44 the number in the corresponding period of last year. The causes of 49, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 39·1 and 40·4 per 1000 in the two preceding weeks, declined again to 36·1 during the week ending March 27th. During the past twelve weeks of the current quarter the death-rate in the city has averaged 40·3 per 1000, the rate during the same period being 18·5 in London and 22·3 in Edinburgh. The 242 deaths registered in Dublin during the week under notice showed a decline of 29 from the number in the preceding week, and included 67 which were referred to the principal zymotic diseases, against 61 and 74 in the two preceding weeks; of these, 37 resulted from measles, 19 from whooping-cough, 7 from diarrhœa, 1 from small-pox, 1 from scarlet fever, 1 from diphtheria, and 1 from "fever." These 67 deaths were equal to an annual rate of 10·0 per 1000, the zymotic death-rate during the same period being 1·6 in London and 5·2 in Edinburgh. The fatal cases of measles, which had been 43 and 46 in the two preceding weeks, declined to 37 last week. The deaths referred to whooping-cough, which had been 9 and 20 in the two preceding weeks, were 19 last week. The mortality from scarlet fever and from "fever" showed a decline from that recorded in the preceding week. The 242 deaths in Dublin last week included 49 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons were below those recorded in the preceding week. Six inquest cases and 5 deaths from violence were registered; and 66, or more than a fourth, of the deaths occurred in public institutions. The causes of 18 or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL J. J. MORRIS has assumed Medical Charge at Citadel Barracks, Dover. Surgeon-Major North has joined at Woolwich for duty, and Surgeon-Captain C. W. Reilly will join at Woolwich during the month of April. Surgeon-Major W. D. A. Cowen proceeds from Cork to Portsmouth, for duty. Surgeon-Major R. L. Love has been ordered to proceed to Dublin for duty. Surgeon-Lieutenant-Colonel Townsend will shortly embark for India.

INDIA AND THE INDIAN MEDICAL SERVICES.

The under-mentioned officers of the Army Medical Staff on arrival from England have been posted as follows:—Surgeon-Major Heffernan, Poona District; Surgeon-Major Jencken, Poona District; Surgeon-Major Drury, Bombay District; Surgeon-Major Hewett, posted to the Nagpore District; and Surgeon-Captain Taylor has been transferred to the Mhow District from the Aden District.

The following retirement is notified subject to Her Majesty's approval:—Surgeon-Lieutenant-Colonel Alexander Kenneth Stewart, Bombay Establishment, the 4th (Prince Albert Victor's Own) Regiment of Bombay Cavalry (Poona Horse).

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff Surgeon John P. J. Coolican to the *Wildfire*, additional for the *Sans Pareil* Surgeons: C. H. Rock to the *Undaunted*, Daniel J. P. M'Nabb to the *Edgar*; and Robert Hickson to the *Philomel*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major W. R. Dambrill-Davies to be Surgeon-Lieutenant-Colonel.

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-fourth session of the Army Medical School, Netley, commences to-day, Friday, April 2nd. The session will be attended by twenty-one Surgeons on probation, fourteen for the Army Medical Staff and seven for the Indian Medical Service. The following are the names of the Surgeons on probation in the order of merit as settled at the London examination:—

ARMY MEDICAL STAFF.

1. S. L. Cummins.
2. C. H. Hopkins.
3. J. McArdle.
4. P. Mackessack.
5. L. J. C. Hearn.
6. J. McD. McCarthy.
7. E. Brodribb.
8. J. G. Walker.
9. H. G. P. Stallard.
10. R. D. Jephson.
11. H. L. W. Norrington.
12. J. Poe.
13. J. Crean.
14. A. W. N. Bowen.

INDIAN MEDICAL SERVICE.

1. J. G. P. Murray.
2. S. Anderson.
3. F. H. G. Hutchinson.
4. J. L. Marjoribanks.
5. J. A. Dredge.
6. R. W. Knox.
7. A. Fenton.

THE TURKISH ARMY ON THE FRONTIER.

That the Turkish soldier is a formidable fighter has been long known, but it will be a matter of surprise to most people to learn from the military correspondent of the *Times* that Turkish organisation has made rapid strides during the last few years, especially in the matter of military railways and hospitals. Writing from Salonika with Edhem Pasha's force the correspondent refers to the creditable state of the Medical Service. He says: "The main hospital here is as good as many in Europe and has a large reserve supply of beds and medicines; the doctors are properly trained, and the ambulances well equipped and officered. A very reasonable order has just relegated all the Christian military surgeons to the depôts, while the fighting line is to be supplied with Mahommedans only. A little dysentery is the only disease from which the entire army of occupation, more than half of which has been brought from the distant provinces of Anatolia, has suffered."

THE HEALTH OF THE ARMY IN INDIA.

The *Spectator* of the 27th ult., in one of its editorial notes on current events, in referring to this subject makes some very pertinent remarks. After alluding to the lamentable prevalence of venereal disease among the European troops serving in India it says that, under these circumstances, it is the imperative duty of the Government to retrace its steps and allow the medical profession to suggest indispensable legislative precautions, which it by no means follows should be of the old kind. Our contemporary adds: "We have never been able to understand why on this subject the right of India to legislate for herself should be overridden. If legislative action with regard to sexual morality is independent of race, climate, and circumstances, how do we justify ourselves when all over India we legalise polygamy?"

The *Broad Arrow* says: "In order to meet the strain on the Indian Medical Service caused by officers being required for famine and plague duty the Government of India have sanctioned the employment in that service of Volunteers from the Army Medical Staff, on a special allowance of 300 rupees a month, in addition to their Indian pay and allowances."

The Duke of York went to Portsmouth on March 31st and visited the sick and wounded from the Benin expedition who are now at the Royal Naval Hospital at Haslar. His Royal Highness afterwards lunched with the Inspector-General and the medical officers at their mess.

It is notified in the *London Gazette*, under date March 25th, 1897, that the Queen's Birthday will be celebrated in London alone on Wednesday, May 26th next, and at all other stations, Naval and Military, on Monday, May 24th next.

Notification has been received intimating the departure from Egypt in the s.s. *Menes* of twenty-seven invalids, to arrive at Netley about March 30th.

INFANT MORTALITY IN CARMARTHEN.—The fifth annual report of Mr. L. Bowen-Jones, medical officer of health, on the sanitary condition of the Carmarthen Union has just been issued. The area of the parish is 157,495 acres and the population 24,732. The birth-rate during 1896 was 28·30 and the death-rate 15·97 per 1000. There were 77 deaths of infants under one year, indicating an infantile mortality of 110 per 1000 births. Mr. Bowen-Jones adds that no proper system of drainage existed anywhere in the district, and that, with a few exceptions, no practical steps have been taken towards improving the water supplies of the locality, notwithstanding the numerous complaints of scarcity of water which have been sent to the council.

FASCINATION OF SERPENTS.

To the Editors of THE LANCET.

SIRS,—Any popular so-called prejudice, if long continued, probably is founded upon some matter of fact, although this may not have been demonstrated. This was the opinion of Sir Benjamin Brodie. That some animals have the power of paralysing others which they prey upon is a matter of direct observation. A rabbit will remain perfectly motionless in the presence of a stoat, and without moving will allow a hole to be made through the skull at the back of the head. We may suppose that the power of feeling, as of motion, is for the time gone. Dr. Livingstone felt no pain when seized by a tiger. I have seen a mouse remain perfectly motionless under the gaze of a cat. When excited the cat's pupil becomes dilated. On one occasion in the evening I saw a cat in an excited state retire to a shady place where it could no longer be seen, but presently I saw two small red globes fixed upon me. I once saw the same less defined in the eyes of a kitten, but it is very difficult to get their eyes fixed when near. A general officer who has seen long service in India informed me that on one occasion a large serpent had got into a house and taken refuge in a cellar. Being a soldier, it was suggested that he was the proper person to dislodge the intruder. He took a spear and looked through a hole in the wall of the cellar, but saw no serpent. Presently two small red globes were fixed upon him. These he supposed to be the serpent's eyes and thrust his spear, as he thought, between them. The spear caught the serpent just behind the head and killed it. My principal object in writing is to ascertain from our friends in India, if possible, through the columns of THE LANCET, the information which I have in vain sought for here—viz: (1) whether serpents have a tapetum lucidum; and, if so (2), whether it is supposed to be erectile; and (3) whether it can have anything to do with the fascination which they are supposed to exercise over their prey. The reflection from the *convex* cornea in front of an eye must, of course, not be confounded with that from the *concave* tapetum at the back. In one case the reflected light is dispersed, and in the other it is concentrated and brought to a focus to suit the wants of different animals. Hitherto the functions of the tapetum lucidum have scarcely been recognised. In the preparations intended to illustrate these in the museum of the Royal College of Surgeons of England they are placed upside down. Had this been their natural position the tapetum would have been useless for the purposes for which it is intended.

I am, Sirs, your obedient servant,

HENRY LEE.

Queensborough-terrace, Hyde-park, W., March 17th, 1897.

THE STRUCTURE AND FUNCTION OF THE AURICULO-VENTRICULAR ORIFICES.

To the Editors of THE LANCET.

SIRS,—In the last paragraph of his first lecture on Some Points in the Pathology of Heart Disease, published in THE LANCET of Feb. 27th last, Dr. Starling states that "owing to the arrangement of the muscular fibres of the heart there is a strong circular band of fibres round each of the auriculo-ventricular orifices." In a paper published in the St. Bartholomew's Hospital Reports, vol. xxiii., 1887, I showed from the masterly dissections of Pettigrew[1] and those of Savory[2] and Quain,[3] and also from my own dissections, that no such sphincter arrangement of muscle exists either around the auriculo-ventricular orifices or enclosing the heart in the plane of these orifices. Indeed, it is easy to see in a heart which has been boiled that the arrangement of the muscular fibres is such as to keep these orifices open in systole. The figures in my paper show that if transverse sections are made through the ventricular walls, beginning just below the plane of these orifices, while in the orifices themselves only the vertical fibres of the first and seventh layers are found, as the sections advance towards the middle of the ventricular wall, all the seven muscular layers are found to be present, and it is at the middle third of the ventricle that fibres are seen having a transverse arrangement. Further, the simple experiment of boiling the heart destroys the fibrous tissue surrounding the auriculo-ventricular orifices, and in the case of the left auriculo-ventricular and aortic orifices causes these apertures to run into one and form a figure of 8, thus showing the entire absence of any circular band of muscular fibres. Some years ago M. Onimus[4] attempted to show that the auriculo-ventricular openings are completely closed in systole by muscular (sphincter) action; but even with regard to one of these openings he himself says: "Si, pour l'orifice auriculo-ventriculaire, on peut admettre des fibres circulaires formant des sphincters, pour l'orifice gauche cette expression n'est pas très-juste, car cette dénomination suppose un muscle annulaire, et nous avons vu qu'une partie de cet orifice était complètement fibreux." This is still further proved by making a vertical section through the junction of the posterior wall of the aorta and the anterior portion of the left auriculo-ventricular ring. At this point the densest fibrous tissue is found, which represents the so-called "heart bones" in some animals. If we assume, for the sake of argument, that a circular band of muscular fibres does exist, which surrounds the auriculo-ventricular orifices and thus encloses rings formed of dense, strong, pliable, fibrous tissue—for all the anatomists I have quoted agree in thus describing them,—when this hypothetical muscular band contracts it may possibly alter the shape of the orifice in one direction or another, but by so doing it in no way causes any diminution in the area. If a ring of whalebone—which, being formed of dense, tough, pliable material, very fairly resembles the fibrous ring of an auriculo-ventricular orifice—be encircled by an elastic band or by the fingers it will be found impossible to alter the area, the only effect produced being an alteration in the shape. I have dwelt almost entirely on the anatomical side of the question, but the mathematical and physiological arguments against the existence of a sphincter arrangement of muscular fibres surrounding the auriculo-ventricular orifices have been fully discussed by the late Dr. Herbert Davies in his papers[5] "On the Law which Regulates the Relative Magnitude of the Areas of the Four Orifices of the Heart," and on "The Four Orifices of the Heart."[6]

I am, Sirs, yours faithfully,

Finsbury-square, March 27th, 1897. ARTHUR DAVIES.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—I was very glad to receive Dr. Dudley Buxton's support in my endeavour to bring about a general improvement in the apparatus used for the administration of anæsthetics, and to learn that the advisability of sterilising inhalers has received his attention. Correspondence has reached me both from the United States and Canada showing that danger from inhalers had been observed by others in the Western Hemisphere, and that attention had been directed to it before my communication to THE LANCET of Feb. 20th. A leaflet from the *Montreal Medical Journal* of May, 1895, has been sent me by Dr. James Bell, who, in recommending a simple form of ether inhaler, uses the following vigorous language in condemnation of one formerly much in use: "The Clover inhaler, which is now so much in vogue, possesses all the disadvantages which it is possible for an ether inhaler to possess. It is impossible to cleanse it. Patients go on, one after the other, respiring through the same filthy mask and the same rubber bag, each one adding his quota of mouth secretions, perhaps syphilitic, cancerous, or tubercular. Tubercle bacilli must frequently be deposited on its walls and vomited matter saturates it from time to time, not to speak of the absolute impossibility of sterilising the mouthpiece to correspond with the precautions which we take with all the other substances coming into close contact with the field of operation. It seems strange that with the knowledge of bacteria which has been accumulating for years, and our very strict precautions, based upon this knowledge, to avoid wound infection in

Hosted by Google

surgical operations, that there has not long ago been devised some means to provide an aseptic inhaler, and one which could be cleansed of the secretions and exhalations of one patient before applying it to the face of another. It is simply horrible to contemplate the use of a Clover inhaler and bag which has already been used on the face of hundreds of other patients, and without any possibility of properly cleansing it, either by heat or chemical sterilisation." Thus, whilst I, in this centre of civilisation, have been mildly urging reform and gently suggesting a change in anæsthetic apparatus, my colonial friend has forestalled me by nearly two years in an onslaught which for dash and courage reminds one of the long lost "Rupert of debate."

My colleague Dr. Silk has done me the honour of discussing my paper in THE LANCET of March 20th from an "anæsthetist's point of view" in a very temperate article, though he must be regarded as holding a brief for the defence. What he says is perfectly true, that pneumonia from septic wound infection is practically removed from surgical practice; but surely this is all the more reason that direct lung infection, such as the case I quoted, rare though it may be, should be more strictly guarded against than at present. His argument against the bacillary origin of pneumonia would not, I am afraid, be accepted by any modern physicians, who are now beginning to classify pleurisies according to the particular organism exciting the effusion. It is sad to think anyone could now be satisfied with the view that the only relation of germ-infection to pneumonia is that the "conditions and secretions of pneumonia furnish very suitable media for the growth of the organisms in question." I will only state with regard to this remark that this was precisely the argument used by the older surgeons when antiseptic surgery was first introduced. They tried to teach us that the bacteria of suppuration were the result, not the cause, of the process. His third argument, that because in their concentrated form chloroform, ether, and alcohol are fatal to bacilli, therefore the masks which are subjected to a dilute vapour would be free from living organisms, is not one that would hold, seeing how difficult it is to destroy these organisms. Surely physicians would long ago have cured all cases of phthisis by the aid of their friends among the anæsthetists if the vapour of any of the drugs used for producing anæsthesia could be trusted to destroy tubercle in the lung. In the end, however, Dr. Silk and I are in perfect agreement that there is still room for improvement in inhalers, and he has long been at work to produce an instrument capable of being sterilised, though perfectly conscious that he could never have done any harm by one that was not capable of being absolutely cleansed. His inventive genius has broken loose in spite of his arguments, and he has been impelled to produce an instrument his reasoning shows is quite unnecessary. He has travelled from a leather mask, through a celluloid inhaler, up to a metal face-piece, and he ends by saying of this: "One of the advantages which I claimed for it being that it met with the demand for an inhaler which could be subjected to the same aseptic treatment as the instruments employed in the operation." Could any two persons be in more absolute harmony? Unfortunately, the ladder by which Dr. Silk ascended still stands against the wall, and the celluloid masks with their septic flannel linings and sponges are still in common use. Some time ago I proposed an Instrument Destruction Committee, to have power to destroy all instruments out of date, and so relieve hospital surgeons of having to operate with instruments invented several generations before. I think the Society of Anæsthetists would do good work by appointing a committee to report on inhalers meeting the requirements of modern surgery, and at the same time empower it to do what is possible to stamp out those belonging to the septic era. My own suggestion, that toughened glass would be the best material for a mask, has, according to Dr. Buxton, been anticipated by Vajna of Budapest, and since this invention has been so highly spoken of I hope we may soon see specimens in use in London.

I am, Sirs, yours faithfully,
R. CLEMENT LUCAS, B.S. Lond., F.R.C.S. Eng.,
Surgeon to Guy's Hospital.
Wimpole-street, W., March 29th.

To the Editors of THE LANCET.

SIRS,—The question indistinctly asked by Dr. Florence Nightingale Boyd in your last issue arises only from the strange tendency there seems to be to forget or ignore in one generation the facts established in that preceding it. It cannot be more than fifteen years since the following facts concerning ether as an anæsthetic were proved beyond dispute: 1. That during its administration the secretion of urine is suppressed. 2. That in damaged kidneys this temporary suppression sometimes becomes permanent. 3. That in certain diseases where structural alteration of the kidneys becomes almost a matter of course, as in large tumours of the uterus and chronic syphilis, rapid and fatal pneumonia or suffocative pulmonary œdema, resulting from the use of ether, adds greatly and unnecessarily to the mortality of operations. 4. That ether is a far more fatal anæsthetic than chloroform, only its victims die some days after the administration, and there are no inquests.

I am, Sirs, yours faithfully,
Birmingham, March 29th, 1897. LAWSON TAIT.

THE RETURN OF MIDWIFERY CASES IN POOR-LAW UNIONS.

To the Editors of THE LANCET.

SIRS,—As many persons seem to be interested in a return of midwifery cases in Poor-law unions for which I have given notice, I shall be obliged if you will allow me to inform them through the columns of THE LANCET that I have received information from the Local Government Board that they cannot at present grant the return owing to the pressure in the statistical branch of the Board, where the work is considerably in arrear and many returns are wanted, particularly in connexion with the Local Taxation Commission. There is no prospect of obtaining the return except as an unopposed one, and as no useful purpose would be served by keeping my notice on the paper I have no alternative but to withdraw it. I am, Sirs, yours faithfully,
House of Commons, March 25th, 1897. J. H. JOHNSTONE.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—The question raised by Mr. W. G. Thistle as to whether acquired characters are or are not transmissible is one of immense importance to medical men, but it is one which has not received the attention it deserves from them. Rightly or wrongly, very many—I believe the vast majority—hold the opinion that acquired characters—e.g., the effects of injury or disease—are transmissible, and in medical literature one constantly meets statements implying this belief. For instance, not long ago an ophthalmic surgeon advised his students to pay increased attention to the eyes of children, for, argued he, these young people have yet to bear offspring, who will suffer from the transmitted effects of parental disease; whereas the effects of disease in the aged will not afflict an unborn generation. Again, "M.R.C.S., L.S.A.," writing in THE LANCET of March 27th (p. 931), tells us of a hare-lip which resulted, as he supposes, from the circumstance that the pregnant mother was frightened by a hare. In the words of Mr. Herbert Spencer, "Clearer conceptions of these matters would be reached if, instead of thinking in abstract terms, the physiological processes concerned were brought into the foreground." It is constantly forgotten that an animal (a man, for instance) is not the offspring of the whole of his parent's body. He develops out of a very minute portion of it only—the germ cell. His eyes are not the offspring of his parent's eyes, his legs have not origin in his parent's legs, and his brain is not descended from his parent's brain; but every portion of him arises solely from the germ cell, which, so far as we know, is indebted to the other cells only for shelter and nutrition. This consideration renders unbelievable the hypothesis that acquired traits are transmissible. Suppose, for instance, a man injures his eye or receives such injury to his brain that epilepsy supervenes; then, if his acquired character is to be transmitted, his spermatozoon, situated far distant, must be so structurally altered, so profoundly modified in a particular direction, that long after separation from the parent organism it will proliferate into an organism which has, inborn, the peculiarity which the parent acquired. By what machinery is this modification of the germ cell brought about? The case for the transmission of such maternal impressions as "M.R.C.S., L.S.A.," chronicles is even harder. What magical influence, does he suppose, emanated from the brain

Hosted by Google

cells of the mother and so affected her embryo, situated on the other side of the placenta and at the end of the long umbilical cord, that a hare-lip resulted? It must be remembered that it is not maintained by those who deny the transmissibility of acquired characters that changes acquired by the parent are incapable of influencing the germ cells; but it is strenuously maintained that they do not influence the germs in such a manner that *particular* changes in the parent are reproduced in the child. It is true that at first sight it seems only reasonable to suppose (for instance) that if a man strengthen his muscles by exercise his children will be the stronger, or if he be weakened by disease his children will be the weaker; but, as a matter of fact, though a fierce controversy on the subject has long raged, and though the phenomena of nature have been ransacked, no clear and indubitable example of the transmission of an acquired character has yet been recorded. Syphilis and phthisis, which are instanced by Mr. Thistle, do not touch the point at issue. Similar effects arise in both the child and the parent merely because they are both infected with the same species of pathogenic micro-organism.

I am, Sirs, yours faithfully,

Southsea, March 29th, 1897. G. ARCHDALL REID, M.B. Edin.

*** Dr. T. Frederick Pearse writes recommending to our readers in connexion with this subject a perusal of Dr. Archdall Reid's recent work on "The Present Evolution of Man," and adds, "I think Mr. Thistle, if he reads this, will see reason to conclude that acquired lesions cannot be transmitted."—ED. L.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—The letter of "For Registration" emphasises only too horribly the intolerable evil of existing conditions, about which there is, however, no difference of opinion. The only question is, Does registration provide a rational and effective remedy? If we opponents of the Bill were imbecile enough to argue, as "For Registration" assumes, "that the poor should pay a medical man," or if it were true that unless they pay for medical attendance they must go without it and be content to fall into the hands of midwives, we should welcome this Bill as offering at least a decided improvement, however inadequate to the needs of the case. For those, however, who have no eye to moneyed interests of profession, obstetrical society, or incorporated midwives' institute (whatever under heaven that may be), but who have at their hearts only compassion for the multitude—a single-minded anxiety for the safety and health of their sisters among the poor—it seems to me that the whole matter turns on the one point of the pretended total impossibility of securing in any conceivably practical manner the same quality of aid in the perils of childbed for the poor citizen as wealthy citizens are careful to engage for themselves. If, on the contrary, such an aim can be shown to be attainable and without the creation of any new agencies, then I contend earnestly that any scheme falling short of this is no better than an unworthy tinkering with the mischief, a penalising of mere poverty as such with avoidable risks to health and life—by the very State, too, that poses with its Poor-law as the great "guardian of the poor"; and, finally, a meanly ungenerous proffer on the part of property-owning legislators—moved mainly by others we wot of with axes to grind—a proffer of a "cheap and nasty" article, whose sole recommendation is its cheapness, and which they would disdain to use for themselves. In this view of the situation I crave permission to formulate more fully a constructive policy that I submit would abundantly meet every requirement, and would effect generally, as it has done where it is in even partial operation locally, the total extinction of the midwife as the "unfit."

First, then, let certain permissive powers—already possessed by boards of guardians and enumerated shortly in my letter in THE LANCET of Feb. 27th—be made general and obligatory. Let it then be proclaimed by the fullest public advertisement throughout the land that every woman in circumstances requiring such medical relief can be supplied with an order for medical attendance in confinement, which she may present to the medical man of her choice and which will be honoured by the guardians; that in case of sudden emergency the same liability of the guardians will hold good without any order; that this, as being the statutory right of every impoverished citizen, involves no disqualification, social or political; that in case of anyone temporarily embarrassed—e.g., by loss of employment—and too proud or too honest to accept such gratuitous service, it will be provided by the guardians on loan, to be refunded as soon as times become good enough. Thus by a mere stroke of the pen we provide at once for all the poorest. The fees for these State patients would be fixed, as now, by the State. The medical profession is a monopoly created by the State in the interests of the public. There could be, to my thinking, no just ground of grievance to those enjoying all the benefits such monopoly and State recognition confer if it were made a condition that its members should act upon these calls of the State and accept the fees regulated by the State.

For those of the people less sunk in poverty and requiring only to be helped to help themselves the Government should immediately create machinery for extending throughout the kingdom correlating and organising dispensaries, maternity hospitals, and maternity clubs, either voluntary or subsidised, or purely municipal. To all of these the beneficiaries would be required to contribute by fixed payments, in anticipation of the event, a certain part of the cost of attendance. The choice of her attendant would rest with the patient, who would be supplied with an order from the institution. If voluntary support were insufficient, State aid from rates or taxes would be needed, with concurrent public control by parish council or otherwise. With regard to the floating part of our population, under a proper organisation of these institutions, whenever a family moved into another district payments made to the club or dispensary of the previous locality could be transferred to the newcomer's credit with the analogous institution at her fresh quarters.

It will be seen that this extension of the sphere and operation of State medicine would be much on all fours with our system of State elementary education, the clubs, &c., in the one case corresponding to the schools in the other; and just as before the days of free education guardians paid school fees for children (without pauperisation) of parents too poor to afford them, so it might be found advisable to relate the Poor-law unions to the local machinery for medical aid to the poor, so that guardians should pay into these agencies for confinements of women too poor to raise the regulation contributions.

Until some serious attempt to tackle the problem in a bold and statesmanlike way has been made and has failed I confess I cannot understand any one lending himself—and still less herself—to such a half-hearted measure, a piece of quasi-benevolent but essentially contemptuous and degrading class legislation for which the utmost that can be said is that it proposes to substitute for a very glaring evil another just as real, but not so bad.

I am, Sirs, yours truly,

Streatham, March 23rd, 1897. THOS. M. WATT.

"A SUCCESSFUL SOCIETY!!"

To the Editors of THE LANCET.

SIRS,—You have paid the highest compliment in your power to the arguments in my letter of March 23rd, for in your issue of to-day you suppress the letter and then misrepresent its contents. I never said that anybody had done things they were not licensed to do. I said that being licensed to do them they did do them. "Words mean what they do mean, and not other things," and my words were clear. Those who support vivisection are wise to avoid legitimate controversy, for if they venture into that arena they are lost. They cry aloud and call their adversary names, which is easier than answering him, but it does not advance truth and is not a very scientific method. Hysteria is not argument. Should you, however, at any time take heart to argue the question with fairness and courtesy I shall be ready to meet you in a like spirit.

I remain, Sirs, your obedient servant,

STEPHEN COLERIDGE.

Egerton Mansions, South Kensington, March 27th, 1897.

*** Mr. Coleridge has stated in a letter to H.R.H. the Prince of Wales, with regard to the Prince's Hospital Fund, that animals "are slowly cut up alive without even the pretence of anæsthetics in many of the laboratories attached to

Hosted by Google

those hospitals." The Home Secretary has stated in the House of Commons that the certificate allowing experiments upon animals without the use of anæsthetics is only granted for inoculations and similar trivial operations. "Words mean what they do mean, and not other things." How does Mr. Coleridge reconcile his words with truth? Hysteria is not argument.—ED. L.

THE GENERAL PRACTITIONER IN THE UNITED STATES.

To the Editors of THE LANCET.

SIRS,—To the average general practitioner in Great Britain the prospects of success in medical practice may seem at times somewhat gloomy; it may therefore perhaps be some slight consolation to him if he will contrast with his own hardships a picture of those which have to be endured by his professional brethren in this land of liberty, where the distinction between a profession and a trade seems oftentimes to have totally disappeared.

To begin with the licence to practise. The obtaining of a degree has until quite lately been a matter of such ease, owing to the competition of so many schools and colleges, that those who append M.D. to their names are in a greater proportion than 1 to every 500 of the population. There is but one medical diploma—that of M.D.—and each medical school has the power of granting this degree to its own students after a course of study which is regulated solely by the ideas of its own particular staff. The length of this course until recently has not exceeded three years, and frequently only seven months of each year. Within the last few years many of the best colleges have adopted with pride—which is perhaps justifiable—a four years' course, although there are quite a number, including Yale University in New Haven, Connecticut, which still require only three years; in many cases, also, only one year's actual attendance at the school was necessary, experience under a reputable physician being accepted as sufficient. The holding of the posts of clinical clerk and surgical dresser are nowhere considered necessary, so that practical experience is undoubtedly wanting. In addition to the first-class medical colleges, there are and have been a vast number of institutions of very small reputation whose existence has often been quite ephemeral and whose degrees were conferred after courses of study from two years downwards, so that the most unambitious individual could gratify his wish for a diploma without even abandoning any occupation or business in which he might be employed. Consequently only the initiated can tell whether a certain degree is worth anything or not, as in order to ascertain the school of graduation one must consult a work known as Palk's Medical Directory, which is simply a catalogue of all who profess the healing art, including irregulars of every description. This work usually appends to each man's name his place of graduation if he be willing to give the information; it then remains to look up the status of the particular school. This work, of course, is not reliable, as the compilers invariably take a man's word about himself and do not profess to give any further guarantee of his genuineness. In consequence of this past general laxity in medical education the ranks of the profession have become overcrowded and the status of many of its members very low.

Within the last ten years, however, there has begun an energetic movement of reform, and many States have adopted laws for the regulation of medical practice, insisting that for the future a medical man wishing to practise within a particular State must satisfy the medical board of that State that he possesses a diploma from a reputable college within its boundaries, or in default thereof must pass the examination set forth by the board. Here we come to a peculiar feature which makes it appear as if the profession of each State was more jealous of outsiders, however eminent, than of irregulars within its borders, for nearly all the laws agree in one respect—instead of admitting any medical man whose diploma is of unquestionable merit, they require everyone alike to pass their own particular examination, whether the applicant be a graduate of the highest school in the land or an itinerant herbalist, so that the graduate of Belle Vue Hospital Medical College, New York, or Harvard University, Boston, if he wishes to practise in Baltimore or Philadelphia must spend several months working for his examination in subjects like botany, chemistry, &c., and must also pay a fee more or less heavy. In Pennsylvania this absurdity is extreme, as the State board apparently has no confidence in any of its own schools, some of which are undoubtedly in the front rank. Accordingly it requires its own graduates, as well as all outsiders, to pass the examination alike, even if they have only just taken their degree in the same subjects and were examined by many of the same professors who sit on the board. The regular practitioners may join the State medical society, which, if it happens to have stringent rules as to admission, will confer on him its hallmark of respectability, but as there are usually in addition a homœopathic medical society and an eclectic medical society in the same State the advantage is not perhaps so great as it appears, particularly as the ordinary layman does not know anything about such matters.

The prescribing chemist, who advertises a proprietary remedy for every ailment or symptom, flourishes here even more than in Great Britain, and if he cannot persuade the sufferer to patronise secret formulas will not hesitate to offer him the modern compressed preparation which was intended for a more orthodox prescription. On the other hand, we do not have much of the "provident dispensary" which is usually run for the profit of one man; and there is not the enormous waste of misapplied medical charity which every city in England tolerates.

It speaks well for American "grit" that things are not even worse than they are, and one can therefore have good hopes for the future; but at present to the English medical man who has ideas of starting for this field there is only one good piece of advice—"Don't."

I am, Sirs, yours faithfully,

March 22nd, 1897. A BRITISH EXILE.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Trafford Park and Heaton Park.

THE "outrage" you deplore in THE LANCET of March 27th will, it is pretty certain, be perpetrated, and Manchester, with the neighbouring borough of Salford, will have to bear as they best may the loss of their largest and most valuable "lung." It may be doubted whether those members of the Corporation who voted against acquiring an open space "of absolutely incalculable value," as you justly say, have had even yet the wit to discover the blunder they committed. This will appear when their tactics with regard to Heaton Park are considered. It is still in the market, and although perhaps less favourably situated than Trafford Park it would confer great benefit to the community of Manchester if it were preserved from the inroads of the builder. Time will show whether the City Council intend to allow this the last opportunity of acquiring a park worthy of the name to fall through (for the supply of open spaces is exhausted), or whether they will rise to their duty and secure it for the benefit of this generation and of those that will follow us.

Manchester Adult Deaf and Dumb Institution.

Something has been done by lip-reading and other methods to make communication of the deaf and dumb with their fellows less difficult and so to alleviate a little their life of solitude, while the education of deaf and dumb children up to the age of sixteen years is now compulsory. After this period such societies as the Manchester Adult Deaf and Dumb Institution, which held its annual meeting on March 26th, are specially useful by providing for the deaf and dumb—in the words of the report—"religious services, visiting them in sickness, assisting them to obtain employment to earn their livelihood, and by occsionally granting temporary relief." At the Institute in Grosvenor-street lectures and other meetings are held in the reading-room, where papers, books, and periodicals are kept. The Lord Mayor, Alderman J. F. Roberts, who was in the chair, asked, "What would such afflicted individuals as the deaf and dumb do without such an institute, which was a church, a school, and a club combined?" There is no question as to its work being useful, but it has not gained the support of the benevolent as it should have done. The committee say

Hosted by Google

they need an annual income from subscriptions and donations of £500 to carry out the work efficiently, while in 1896 they received only £278; but there still remained a balance in hand on the fund of the Lady Mayoress's garden party which took place in the summer.

Ancoats Healthy Homes Society.

It is a wholesome sign that in one of the poorest and most crowded of the industrial districts of Manchester a large audience of the residents should have met together on Wednesday, March 24th, to hear from our *confrère* Dr. J. M. Rhodes, the chairman of the Chorlton Board of Guardians, an address on "Pauperism, Past and Present." The Ancoats Healthy Homes Society is an association of working men trying to brighten their own homes and those of their neighbours by entertainments and addresses which those more fortunate than themselves are always ready to give on various subjects. It is one of the offshoots of the Sanitary Association. Dr. Rhodes drew a graphic picture of the condition of the poor in the past, and showed that "the present condition of the workers of to-day was vastly superior to that of former times." By the help of coloured charts he explained the incidence of pauperism and Poor-law taxation, and he pointed out that the ratio of pauperism was greater in the agricultural districts of the East and South than in the mining and manufacturing districts of the North and West. He named over population and drink as the chief causes of pauperism, and urged his hearers to work out their own salvation—to use too common a phrase—by cultivating the old-fashioned, and among a large number almost forgotten, virtues of industry and perseverance, sobriety and thrift.

The Sanitary Committee and Cleared Areas.

At the last meeting of the City Council the consideration of the report of the sanitary committee, dated Feb. 8th, 1897, was resumed. Some members objected strongly to the proposal to build a large lodging-house in Ancoats, which seems unreasonable in face of the fact that twenty-nine registered lodging-houses, with accommodation for between 450 and 500 people, were taken down in connexion with the opening out of Whitworth-street. These people must have some provision made for them. In a large population there will always be single men and women, who are all the more likely to remain or to become decent and respectable if proper provision is made for their lodging and if they are not treated as outcasts and pariahs. But among a section of the City Council there is a strong and unreasonable prejudice against any such provision being made. The present lodging-houses, which are under the control of the watch committee, do not seem to be quite the models they ought to be, for Dr. Dearden said that many of them were veritable death-traps from the "respiratory impurity" of the air in the bedrooms at night. Dr. Daly thought that if Mr. Boyle—the principal objector—and his supporters had seen the London lodging-houses visited by the committee they would not allow sentimental objections to weigh with them; but this gentleman—who is a member of the watch committee and perhaps objects to the sanitary committee touching the lodging-house question—retorted, "It was all very well for the medical members of the council to air their fads." In this case the fads are decency and sufficient ventilation. Alderman McDougall very properly insisted on the importance of securing the thorough sanitation of houses where large numbers of people are wont to congregate. In the end the report of the committee and the recommendations it contained were adopted.

March 31st.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Durham University.

Of the thirty candidates who entered for the Extra Arts Examination at Durham University a few days ago only eleven succeeded in satisfying the examiners. All students not graduates in arts who intend to graduate either in medicine or in science at this University are required to pass this examination, and it is somewhat astonishing how high the percentage of failures continues to be. Of the eleven men who passed on this occasion nine were prepared by the same tutor, indicating apparently that failure is due more to a want of knowledge as to the nature of the test than to a deficiency of education.

Dr. Arnison's Last Clinical Lecture.

The theatre of the Royal Infirmary, Newcastle-upon-Tyne, was well filled on March 24th by Dr. Arnison's colleagues and students to hear his last lecture. He chose for his subject what he called "some of his fads," and showed a large number of most interesting cases, including many in which aggravated club-foot had been treated by Phelps's operation, and the results were certainly most excellent. Dr. Arnison also showed a number of patients who had been treated with the actual cautery for ulceration of the cartilages of the knee-joint—some of them a good many years ago. Not only had the joints been cured, but the movements of them in many cases were perfect. Dr. Arnison has been connected with the infirmary for upwards of thirty years, and in retiring carries with him the regard and respect of his colleagues and the affection of his students.

Death of Mr. Beatty of Seaham Harbour.

On March 26th this much respected member of the medical profession died at the age of eighty-three years. Mr. Beatty during his long career at Seaham Harbour identified himself with nearly all the institutions of the town. He was surgeon to the hospital established by Lord Londonderry for the use of sailors, surgeon to the Seaham Harbour Volunteer Artillery, a permanent member of the committee of the Londonderry Literary Institution, &c. For some time Mr. Beatty had been ailing, but it was only a very few days before his death that his friends became seriously alarmed.

The Ingham Infirmary, South Shields.

Of the sum of £10,000 which it is proposed to raise for the enlargement of the Ingham Infirmary at South Shields, in commemoration of the Queen's long reign, upwards of £8000 has already been subscribed, and Mr. H. Griers, the architect, has been instructed to advertise for tenders for the erection of a new wing.

March 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chair of Public Health for Edinburgh.

THE Scottish Universities Commission have issued amongst other draft ordinances one for the establishment of a separate chair of public health in the Edinburgh University. The chair is to be called the Bruce and John Usher Chair of Public Health, in recognition of the fact that its establishment has been made possible by the munificence of the two gentlemen whose names it bears. It is ordained that the occupant of the chair shall receive the annual income derived from the endowment, together with such sum out of the central fund of the University as may be necessary to bring the salary up to £600. The Court is given permission to increase the sum to be taken from the general fund. The fees of the students are, as in the other classes, to be paid into the general fund. The patronage of the chair is vested in the University Court.

The Edinburgh Royal College Golf Match.

The annual golf match between the Royal College of Physicians and the Royal College of Surgeons of Edinburgh, was played last week at Gullane in a hurricane of wind. The surgeons won by seven holes. The match always gives rise to considerable interest.

University of Aberdeen.

This is the first year in which the arts bursary competition and the medical, arts, and science preliminary examinations have taken place in the spring. The examinations opened on Saturday, March 27th. There were thirty-five entrants for the medical preliminary, five for the science, and 126 for the arts examinations. For the bursaries there were 166 competitors. The north tower at Marischal College extension has been completed, but to prevent petty depredations during the construction of the other buildings it has been found necessary to erect a paling, with a temporary gateway leading into the quadrangle. An association is being formed under the auspices of the General Council to raise funds for the further extension and better endowment of the University.

Day Nursery in Aberdeen.

A new institution in Aberdeen—a day nursery for children of working women—has been started in Princes-street, with accommodation for twenty or thirty children.

March 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Patients from Ireland at the Pasteur Institute.

THERE are just now three patients from Ireland being treated in Paris with the famous prophylactic for hydrophobia. The Athlone Board of Guardians, far from sending their patients to the local quack McGovern, have forwarded a recent case of dogbite to the Pasteur Institute under the personal charge of Mr. Shanley, their medical officer. The Local Government Board have written to know why the patient was sent in charge of the medical officer at a cost of £40, in addition to the three guineas per week paid to his substitute, instead of being given in charge to some subordinate official. The guardians have replied that their reason for sending their medical officer was the fact that the patient suffered from occasional epileptic fits. The Board have significantly remarked that the cost incurred in this case will come before the auditor for revision.

Trinity College, Dublin.

Dr. A. F. Dixon, Senior Demonstrator of Anatomy at the School of Medicine of Dublin University, has been appointed Professor of Anatomy at the University College of South Wales and Monmouthshire, Cardiff.

Belfast District Lunatic Asylum.

The medical superintendent of the Belfast Asylum, Dr. Merrick, has just issued his annual report for 1896. The daily average number of patients resident during the year has been 834, an increase of 52 over that of the preceding year; 273 cases were admitted during the year, 33 more than in 1895, and this is the largest number of admissions since the opening of the asylum. During the five years from 1892 to 1896 inclusive 1154 cases were admitted into this asylum, while for the five previous years, 1887 to 1891 inclusive, there were 997 taken in. There were 179 discharges during the year, and 44 deaths (all from natural causes), exactly the same number as in 1895. The general health of the inmates, notwithstanding the overcrowded state of the asylum, was satisfactory, and there were no cases of contagious or infectious disease. The gross expenditure for the year was £21,089 6*s.* 2*d.* The net cost per head for the year was £23 18*s.* 8*d.*

Queen's College, Belfast.

The chair of Natural Philosophy in Queen's College, Belfast, vacant by the resignation of Dr. J. D. Everett, has just been filled by the appointment of Mr. W. B. Morton, M.A. Professor Morton is an old Queen's College student, where he had a most distinguished career. He afterwards went to St. John's College, Cambridge, where he held a very high position, and graduated in the Mathematical Tripos of 1892; at the examinations for the B.A. and M.A. of the Royal University he was first of the first class, and in 1894 he gained the Junior Fellowship in Mathematical Science. Professor Morton's appointment is most popular at Queen's College, where for some time he has lectured as assistant to Dr. Everett.

The New President of Queen's College, Cork.

It is officially announced that Sir Rowland Blennerhasset has been appointed President of the Cork Queen's College. Sir Rowland Blennerhasset is well known in the political world, and some years ago he contested Galway in the Unionist interest. In medical and educational circles generally it was hoped that Professor Corby would have been the successful candidate, as he was regarded as possessing special qualifications which would have peculiarly fitted him for the position. The new President has entered on the discharge of his duties, but has not yet gone into residence, as it is understood that the late President is in such a critical state of health as to preclude his removal.

March 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Debate upon Appendicitis.

A LONG discussion, lasting over two meetings, upon the subject of appendicitis has been going on at the Society of Medical Officers of Hospitals as well as at the Surgical Society. The question for consideration was: How is it possible to know when to operate upon *appendicite à froid*—that is to say, during the period when there are no active symptoms and where the operation would be undertaken only with a view to the prevention of a relapse? M. Merklen narrated three cases of the disease which had occurred in the children of a family most of the members of which had already been the subjects of appendicitis. All the cases had occurred during an epidemic of influenza and were accompanied by a train of symptoms closely resembling those of influenza. He gave it as his opinion that in an attack of appendicitis no one could foresee the chances of relapse or its probable gravity. M. Bissaud reported a curious case, which he called "*appendicite-fantome.*" In this case the patient presented all the classical symptoms of appendicitis, viz., a well-defined tumour in the right iliac fossa, constipation, and uncontrollable vomiting. Operation was deferred for some cause or other, and the patient suddenly developed an attack of left hemianæsthesia, which showed that the "appendicitis" was purely hysterical and the peritonitis spurious. She was cured by a psycho-therapeutic treatment. Later, however, a new attack of pseudo-appendicitis developed and the patient consulted another medical man, who upon operating found the appendix slightly congested. A patient of M. Rendu suffered from similar hysterical crises, with hiccough and profuse hæmatemesis. The appendix was removed and all the symptoms disappeared immediately, indicating that they had been reflex and dependent upon appendicular colic. M. Talamon had seen three similar cases. M. Le Gendre brought forward a table of twenty-five cases from which he drew conclusions favourable to surgical interference. M. Hayem related a case of uncontrollable vomiting, which for a long time he considered as a typical case of nervous vomiting following a febrile attack. He removed the appendix, which was thickened and bound down by adhesions, when the nervous vomiting which had hitherto resisted all treatment disappeared at once. M. Achard and M. Broca communicated the results of a bacteriological examination of the peritoneal effusion in twenty cases of appendicitis, in which suppuration had occurred and in which they had operated. In seventeen cases the bacillus coli communis was found—alone in seven cases, and associated with other pyogenic microbes in ten. For the most part these latter were streptococci; in one case the pneumococcus was present, and in the remaining three cases the bacillus coli was absent. M. Letulle described the lesions of appendicitis, and attributed them to a phlegmonous or gangrenous lymphatic infection secondary to a more or less chronic inflammation of the follicles. He distinguished two types—tuberculous appendicitis, and the appendicitis of Eberth or the typhoid variety. Both kinds were equally likely to end in perforation. In all cases of chronic appendicitis tuberculosis, he thought, should be suspected. The result of this long discussion appears to be that the prognosis in a case of appendicitis is very uncertain and that no one can foresee what may be the result of a first attack. The rules would seem to be: (1) Do not operate for one attack, but watch the patient; and (2) in case of a second attack operate even if the attack subsides favourably, and do not hesitate to remove the appendix *à froid.*

The Microbe of Baldness.

Great prominence has been given in the daily press to a discovery stated to have been made by M. Sabouraud, author of a well-known work on the biology of tinea, and superintendent of one of the laboratories at the Clinic of Dermatology. M. Sabouraud has succeeded in cultivating a microbe which he considers to be the cause of baldness, and which he has found to exist in great abundance in bald people. It invades the periphery of the hair follicles and brings about an influx of leucocytes, which choke the bulb and arrest its development. This is due to a special toxin which it secretes and which, according to M. Sabouraud, has a selective action on the hair follicle. A filtered culture injected into a rabbit is reported to have made all its hair come off.

The Abortion Case: the Sentence.

The interest of the week has centred in the trial of Dr. Boisleux and Dr. de la Jarrige for procuring abortion, the commencement of which I described in my letter of last week. The whole trial has been made the subject of sharp controversy. There were no convincing proofs that abortion

Hosted by Google

had been procured—in fact, the only evidence was that of the midwife, who said that Miss Thomson had come to her for that purpose, saying that medical men had told her that she was pregnant. The opinion of many is that had Dr. Boisleux been anxious to bring on abortion he would have used a simpler method than curetting and would not have operated in the presence of five witnesses, among whom were a servant and a cabman. The Court went into the question of all the deaths which had occurred after operation in Dr. Boisleux's practice for the last five years, although there was no question of abortion in any one of them. A number of witnesses who had been cured by him gave evidence in support of his skill, and everyone looked for an acquittal on the charge of abortion, although it was thought a conviction for involuntary homicide might have been secured. The jury, however, found the two defendants guilty of having procured abortion, and, although they recognised "extenuating circumstances," the defendants were condemned to five years' imprisonment. While sentence was being pronounced Dr. de la Jarrige was seized with a violent attack of angina, and for the space of an hour his life was in danger. The spectators in court burst out into cries of protestation at the verdict and hissed the jury. All the papers consider the sentence much too severe having regard to the weakness of some of the evidence and the irregularities in the indictment, and it is possible that the judgement will be reversed.

The late Dr. de St. Germain.

The death of Dr. de St. Germain is announced. The deceased was surgeon to the Hospital for Sick Children, and was well known for his works upon orthopædics and as the supporter of a method of rapid tracheotomy in which the operation was done in one stage. The method is known as that of St. Germain.

March 30th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Prevention of Cruelty to Children.

THE "Comitato Romano della Società pro Infantiâ" is one of our best institutions, and has this week begun its beneficent career with the rescue of the little waifs and strays of the city abandoned or neglected by their unnatural parents. The first "shoal" of these opportunely "enmeshed" little martyrs drifting down the side-currents of Roman life, to "sink or swim," was pitiable in the extreme—starvation, nakedness, and positive disease appealing to their deliverers with an eloquence beyond words. Most of them had in the first instance to be sent to hospital to recover from the lesions inflicted by hands in no sense parental—hands of the itinerant *impresario* or *exploiteur* disappointed at the proceeds of the day's begging. Many of them, indeed, will require years of careful tendance and rehabilitation to acquire normal development, physical and mental. The Ospedale del Bambino Gesù, the Ospedale di S. Spirito, the Asilo Torlonia, and other well-known institutions have generously allowed their resources to be strained by the "Comitato," but substantial support is required from the well-to-do citizen if the work of rescue is to keep pace with the claims upon it. Above all—and here every sensible Italian is at one with the "Comitato"—let nothing be given to the little mendicant, especially in money. Rather let the sum, however infinitesimal, be sent to the seat of the "Comitato" in the Via Tritone, where it will be duly acknowledged and properly applied. Our compatriots—so many philanthropic Italians assure me—are from their reckless freehandedness the unwitting mainstay of mendicancy in Italy and, *ipso facto*, the most formidable enemy of her societies for its suppression. Indolent almsgiving—the charity, that is to say, that takes no trouble to ascertain deserving cases or (the next best thing) to support the organisations that do—is, indeed, the besetting sin of the Briton abroad, creating far more mendicants than it ever relieves, making the beggar's business a paying one and (of course, unconsciously) becoming responsible for much of that "exploitation of infancy" whose tragic results the "Comitato Romano" and other *comitati* throughout the kingdom are doing their best to mitigate, if not to annul.

The Bacillus of Yellow Fever.

As stated in THE LANCET,[1] Professor Giuseppe Sanarelli of the University of Siena, who now directs at Montevideo the Istituto d'Igiene Sperimentale, of which he was the founder, had, as the result of a year's special study, satisfied himself that he had discovered the bacillus of yellow fever. His researches he embodied in a monograph which has for some time been in the possession of the Accademia Medica di Roma, that body being thus empowered to protect his claim to priority should that claim in the interval have been challenged. The supplementary studies by which he has sought to check the laboratory and clinical work leading up to his discovery are now completed, and the whole series—including the substance of the provisional monograph aforesaid—will be published in three successive *fascicoli* of the Annali dell' Istituto Pasteur. Coincidently with the appearance of the first of these *fascicoli* (that is, within a few weeks' time) he will deliver before the Montevidean Society of Medicine a lecture, accompanied by illustrative preparations, in which the nature of his discovery and the successive stages by which it was arrived at will be fully set forth.

Criminal Anthropology: its Fifth International Congress.

Preparations are already on foot to make the Italian intervention at this Congress as effective as possible. It will be held in 1901 at Amsterdam—not, as announced in some quarters, at The Hague—and on certain days, yet to be fixed, in the month of August. Italy, who justly claims the "science" (so-called) as her own, will be represented by *savants* who, besides holding university chairs specially devoted to it, have the further advantage of ventilating their views in Parliament in the discussions evoked by the estimates of the Ministers of Education and of Grace and Justice. Such are, for instance, Professor Napoleone Colajanni of the University of Naples and Professor Enrico Ferri of the University of Rome, both of whom have been elected to the new Chamber of Deputies—the former for his old seat of Castrogiovanni, and the latter for Gonzaga.

March 27th.

[1] THE LANCET, Jan. 9th, 1897, p. 142.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Antitoxin in Diphtheria.

DR. ZUPPINGER has published a highly interesting report on the antitoxin treatment of diphtheria in the Crown Prince Rudolf Hospital for Children during 1896. In the course of the year there were in all 168 children under treatment for diphtheria, two of whom remained in hospital at the close of the year. Of these patients 136 (i.e., 82 per cent.) recovered, and 30 (i.e., 18 per cent.) died. Eight of the children were admitted in a hopeless condition and died within twenty-four hours, one suffered also from tuberculous cachexia, and one died from pneumonia after scarlet fever; if these cases were deducted from the preceding figures the general mortality would be only 12 per cent. From 1894 to 1895 the death-rate for diphtheria in this hospital fell 16 per cent., and from 1895 to 1896 it fell a further amount of 7 per cent. In slight cases quantities of serum containing 1000 antitoxin units were at once injected; in severe cases the amount was raised to 2000 units, and the injections were repeated within twenty-four hours if no mitigation of the diphtheritic symptoms occurred. As a rule, from 1000 to 5000 units were injected in the course of the first day. Dr. Zuppinger divided the patients into four groups: (1) diphtheria of the pharynx, of which there were 91 cases with 5 deaths, or a mortality of 5·5 per cent.; (2) diphtheria of the nose and pharynx, of which there were 24 cases with 9 deaths, or a mortality of 37 per cent.; (3) diphtheria of the pharynx and larynx, of which there were 48 cases with 16 deaths, or a mortality of 33 per cent.; and (4) primary diphtheria of the nose, of which there were 3 cases. The first group included 83 patients—i.e., one-half of the general total—who suffered from diphtheria of the pharynx in the fibrinous form; all of them recovered, 7 of them being children who were not treated with antitoxin. The remaining 8 children of this group suffered from the phlegmonous form of the disease, one of them also from the septic form. The phlegmonous cases were characterised by glandular swelling, diffuse œdema of the neck, inflammation of the pharyngeal structures, and extensive dense exudation on the tonsils and uvula. Within the first twenty-four hours from 3000 to 4000 antitoxin units were injected, after which the symptoms of incipient degeneration of the cardiac tissues disappeared, even in two

Hosted by Google

instances where death seemed to be inevitable. The great value of antitoxin in these cases might be inferred from the fact that none of these patients developed affections of the larynx, and Dr. Zuppinger was of opinion that antitoxin is by far the most efficacious remedy against diphtheria. Of the children who recovered two-thirds showed no rise of temperature after the injections. In 47 cases Löffler's bacilli were found, in 32 cases they were mixed with streptococci and staphylococci, and in 12 cases no bacilli could be discovered, notwithstanding the existence of clinical symptoms of diphtheria. The 24 cases comprised in the second group included 9 patients suffering from the phlegmonous form of the disease and 2 suffering from the septic form. The latter when admitted showed symptoms of the hæmorrhagic diathesis as well as of cardiac degeneration, and they died on the first day; 5 of the phlegmonous cases recovered. The remainder of this group suffered from the fibrinous form of diphtheria of the pharynx and nose; 2 of them died from pulmonary complications, and 1 from parenchymatous degeneration of the myocardium. In the third group, consisting of 48 cases of diphtheria of the pharynx and larynx, the therapeutic value of the antitoxin treatment was strikingly manifested. On admission 16 of these children suffered from stenosis of the larynx, which disappeared after the injections; 14 of them recovered and 2 died from broncho-pneumonia. Among the remaining 32 children of this group primary tracheotomy was performed in 2 cases, secondary tracheotomy in 4 cases, and intubation in 26 cases; 14 of them died. Primary tracheotomy was performed because intubation was impossible on account of the swollen state of the larynx; both these children died from pneumonia. Of the 3 cases of primary diphtheria of the nose constituting the fourth group 1 occurred after measles; antitoxin was injected and the symptoms disappeared. During the first year the general death-rate was 54 per cent., from the first to the second year it was 47 per cent., from the second to the third year 25 per cent., from the third to the fifth year 13 per cent., from the fifth to the seventh year 6 per cent, and from the seventh to the twelfth year 3 per cent. As a prophylactic measure 54 children were injected with from 300 to 1000 units.

Carcinoma of the Rectum.

Dr. Funke, assistant to Professor Gussenbauer, has published an account of 266 cases of carcinoma of the rectum, of which 156 were operated on and 40 died, the mortality being therefore 24·4 per cent. The patients included 181 males and 85 females. In a great many cases the disease followed habitual constipation; in two cases it seemed to have grown on the base of syphilitic scars. It occurred most frequently between the fiftieth and sixtieth years of life; but there were also patients at the age of fifteen and over eighty years. Colloid carcinoma—the most malignant form—occurred before the age of thirty years, and the medullary and fibrous forms prevailed between the fortieth and sixtieth years of life. Among the 266 cases of carcinoma there were 12 epithelial, 162 adenoid, 64 annular, 7 carcinomata of the sigmoid flexure, and 21 colloid carcinomata. In annular carcinomata resection is to be performed only if there are no enlarged lymphatic glands. Temporary resection of the os sacrum gives very easy access to tumours situated high up in the rectum and never causes necrosis of the bone.

Lepra Tuberosa.

A case of lepra tuberosa maculosa et anæsthetica was exhibited by Professor Kaposi at the last meeting of the Vienna Medical Society. The disease commenced some nine months ago with nodules on the left carpal articulation; the nodules were of the size of a pea, they were reddish-brown in colour, and resembled the so-called cutaneous papules in syphilis, for they had a central atrophic depression and crusts. There was hyperæsthesia round the areas of cutaneous anæsthesia, a circumstance which showed that there was an affection of only the extreme peripheral nerve ends. No bacilli have hitherto been found.

Medical Fees.

At the last meeting of the Medical Chamber the following scale of fees was agreed to: A day visit, 3 gulden (about 5*s.*); an evening visit, 4 gulden (6*s.* 8*d.*); a night visit (without carriage), 6 gulden (10*s.*); a consultation, 10 gulden (16*s.* 8*d.*); one hour, 5 gulden (8*s.* 4*d.*); a visit at a time fixed by the patient, 5 gulden (8*s.* 4*d.*); for each additional patient seen in a house, 1 gulden (1*s.* 8*d.*). The visits are to be paid for at once; in cases of very poor people the medical man may make a lower charge at his discretion.

March 21st.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Medical Chambers in Hungary.

THE question whether medical chambers should be created in Hungary is just now greatly agitating the minds of the medical men of this country. The Home Office had prepared a scheme with this object, but before bringing it as a Government proposal before Parliament Minister Perczel very wisely decided to ascertain the views of the Hungarian medical profession. He therefore sent a draft of the scheme to all the medical societies of the country, requesting them to give it their consideration and subsequently to transmit their opinions to the Home Office. Some extracts from the proposed measure will best give an idea of the manner in which it may be expected to work. "Section 1. The medical chambers are established for the purpose of promoting public health and protecting the interests of the medical profession. Section 2. The number, distribution, and locality of the chambers are to be settled by the Home Office. Section 3. Every medical practitioner, active members of the military service excepted, is required to join the medical chamber of his district. ..... Section 15. The President and the other office-bearers of the chamber are elected by secret voting at the general meeting and are appointed for a period of three years. ..... Section 19. The council of honour has to decide disputes occurring between medical men and complaints raised against practitioners, and has to settle questions of medical ethics. Section 20. This council of honour is empowered to sentence the members of the chamber: (1) to be admonished, (2) to be censured, (3) to be fined a sum not exceeding 500 crowns (£20), and (4) to be restrained from exercising their rights in the chamber for a period not exceeding two years." This question of medical chambers is being much discussed not only in the medical but even in the lay press. The profession is divided into two parties, one of which is in favour of rejecting the scheme of the Home Office and is altogether opposed to the creation of medical chambers, but recommends a union of the profession on a system similar to that of the British Medical Association, whilst the other party looks upon the establishment of medical chambers as the one possible and effective safeguard against the further lowering of the social status of the profession. The opponents of the measure point to the fact that most countries of Europe can do without medical chambers, and that even Great Britain, the country which accords a better social standing to its medical men than any other country in the world, has no institution of the kind. On the other hand, those who are in favour of the chambers are of opinion that only such institutions as are founded on a legal basis can have power to proceed against a man guilty of infamous conduct in a professional respect, and they remind their opponents that medical offenders in Great Britain cannot be adequately dealt with by the British Medical Association, but have to be brought before the General Medical Council, on which the requisite powers have been conferred by Act of Parliament.

March 27th.

"A VERY GRAVE SCANDAL."—For a long time the propriety of lodging imbeciles of a certain class in workhouses rather than asylums has been debated. The Eastbourne magistrates had to deal with a more difficult contingency. A prisoner before them would, it was feared, become a dangerous lunatic. The superintendent of the East Sussex Asylum telegraphed that they had no room for the case. Matters were very grave, and on the man's remand an urgent note was sent to the asylum pointing out the gravity of the case. The reply was, "No vacancy; shall decline to admit." So the man was sent to the workhouse, where there were no means of proper restraint. Since then drafts have been made from the East Sussex to other asylums, the accommodation having only just become available. Without endorsing the remark with which this note is headed we may be permitted to inquire—In case the man ran amok at the workhouse and killed someone, who would be responsible?

Obituary.

CHARLES ELLIOTT LEOPOLD BARTON HUDSON,

F.R.C.S. ENG., L.R.C.P. LOND., ETC.,

ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE abrupt termination by death of a promising career is at all times pathetic and saddening, for that which comes as the natural and well-earned rest to the veteran seems to our limited vision hard and harsh in the case of those who are called away in the plenitude of vigour and who have barely crossed the threshold of the portal of fame. Thus has it been with the young surgeon whose death we chronicle to-day, with feelings rendered more poignant by the fact that for several years past he has been a valued coadjutor in the work of THE LANCET, and if therefore we dwell rather fully upon the comparatively uneventful details of his life we think that the account will enable our readers to understand how full and varied such a life may be, although, perchance, he who lived it may not have become known to the larger world outside.

Leopold Hudson came of a family whose genealogy could be traced to Saxon times, and of whom many generations had resided in Ireland. Thus his great-grandfather, Dr. Jonathan Hudson, of Cork, was a physician of some repute and author of two works on the "Philosophy of Medicine," and his eldest son, James Elliott Hudson, also intended for the medical profession, abandoned this pursuit in his student days for that of the Army, serving in the Peninsular and other campaigns. Captain Hudson retired from the Army at the close of the war, and shortly afterwards married, his fourth son, born in 1818, having as one of his sponsors Leopold I., the King of the Belgians, and receiving the names of James Elliott Leopold. This son, together with an elder brother, was rescued from the wreck of the *Colborne* off the coast of New Brunswick, at the mouth of the St. Lawrence, in October, 1838. Besides these youths, only ten were saved out of fifty-four persons on board, the victims including Captain and Mrs. Hudson, with nine of their children, Captain Hudson having embarked for Canada to assume the military governorship of a district in New Brunswick. James Elliott Leopold, who narrowly escaped with his life from the privations and injuries received at this shipwreck, returned to England in 1842, and eventually settled at Bungay, Suffolk, where he lived until his death in 1890. His second son, Charles Elliott Leopold Barton, was born on Dec. 27th, 1862. Educated at home, and intended for the medical profession, he was articled to Dr. Adams of Bungay, and in his eighteenth year entered in October, 1880, as a student of the Middlesex Hospital, with which his whole subsequent career came to be identified.

The exceptional brilliancy of his career as a student speaks well for the soundness of his home training, but he had also great natural gifts, being quick to learn, and endowed with a good memory as well as with much facility and accuracy of expression. He soon distanced most of his compeers, carrying off prizes in nearly every one of the classes he attended from his first to his final year, and also the Governors' prize in 1882–3, and the first Broderip Scholarship in 1883–4. When still a student he was selected in 1882 to be Demonstrator of Physiology, and thus early showed that he had as much aptitude in imparting knowledge as he had in acquiring it. Indeed, he excelled as a teacher, and in the years of struggle for existence which confront most young men who elect to pursue the career of London consultants he gained many pupils who are unanimous as to his teaching gifts. In the medical school he taught pathological histology for some years, whilst during the past two years he had been holding the office of surgical tutor. When the Residential College was founded in 1887 he was selected as its first Warden, and his position here enabled him to hold special tutorial classes for the students under his charge. His attachment to his hospital was heart-whole and never relaxed, and the keenness with which he threw himself into any project on behalf of the students was marked throughout. During his studentship he was a constant attendant at the Students' Medical Society, reading papers and sharing in debates, for he was a ready and fluent speaker, and it was owing mainly to his initiative that the several clubs and societies in the school were amalgamated in 1891–92. He was chosen as honorary secretary of the Amalgamated Clubs, and it was in great measure due to him (aided by Dr. H. C. Thomson and Mr. C. Reissmann) that the *Middlesex Hospital Journal* was started this session. There had been a proposal that the Medical Society (of which he was then President) should take some steps to publish its proceedings, and from this came the idea of founding a hospital journal. During his long illness he often discussed the affairs of this journal and made suggestions for its conduct which were of much practical value.

As regards his hospital appointments, Leopold Hudson in 1884–85 held the offices of house physician to Dr. Cayley and of house surgeon to the late Mr. Hulke. After this he went to Paris for a short time to study there, and then was appointed surgical registrar to the London Temperance Hospital. In 1887 he succeeded Dr. Kingston Fowler as pathologist and curator at the Middlesex Hospital, and for three years did good work in this department. Meanwhile (in 1880) he had obtained the Fellowship of the Royal College of Surgeons of England, and when a vacancy occurred in the office of surgical registrar he naturally was selected to fill it. This appointment he held for four years (from 1890 to 1893), his annual reports being evidence of his industry in this post. In 1893 he became a candidate for the office of surgeon to the Throat and Ear Department, which had become vacant by the death of Mr. A. Hensman, and his appointment to this office secured for him the position on the staff of his hospital for which he had legitimately aspired. In 1895 he was also elected assistant surgeon. He had, moreover, shortly before his staff appointments at the Middlesex Hospital been elected assistant surgeon to the Hospital for Sick Children, Great Ormond-street. His time and energies were thus fully occupied in hospital duties and in teaching; but nevertheless he undertook other duties, the most important being that of secretary to the Royal Commission on Tuberculosis, which held sittings from 1890 to 1895, and for which he worked *con amore*. We have already mentioned his connexion with THE LANCET, which commenced nearly ten years ago, one important part of his work consisting in reporting the debates of the various medical societies, where his habitual attendance made him familiar to many.

Apart from such purely professional work Leopold Hudson had many other interests. He was a keen politician, and even in his student days his ready speech was of no small assistance in election contests, when he worked hard for his "party." He also held the commission of Surgeon-Captain in the Middlesex Yeomanry Cavalry, and had been teacher of volunteer ambulance instruction. He was, moreover, a zealous Freemason. At the beginning of the year 1895 he married Miss Ethel Vaughan Morgan, daughter of Mr. Septimus Vaughan Morgan, and established himself in Harley-street, having fairly embarked on a career which promised to be full of happiness and prosperity. He leaves two children—both sons—the younger born on Feb. 6th of this year. The particulars of the illness which has unhappily brought so promising a career to a close must be briefly told. It commenced in September, 1896, with some obscure symptoms of sensory and motor disturbance in the lower extremities following on chill and fatigue. But he was enabled to resume his hospital duties in October, only, however, to be attacked in a few weeks' time more acutely with paraplegia, which at one time caused great anxiety. From that time till his death he never left his bed, yet throughout retained his habitual cheerfulness and sanguine disposition, looking forward to the time when he would once more be enabled to resume that activity in which his soul delighted. Nor was this hope without some justification, for he was gradually regaining power in his limbs when, on March 24th, a severe attack of abdominal pain, followed by headache, made him feel and express the thought that his days were numbered. But he met this blow with admirable fortitude and composure, in the same spirit as he had borne the long and weary illness through which he had been passing. Hemiplegia and coma supervened, and he died on the morning of the 29th, in the thirty-fifth year of his age. Throughout the whole of his illness he was devotedly attended by his friend Dr. Edward Semple and by Dr. Cayley, as well as by Dr. Hughlings Jackson, Dr. W. S. Colman, and Dr. James Taylor. The post-mortem examination showed that the immediate cause of death was cerebral hæmorrhage, but that the spinal cord had so far recovered as

Hosted by Google

to present no obvious morbid change. It was difficult to account for the hæmorrhage, as the cerebral vessels were perfectly normal. There were numerous calculi in the renal pelves, both kidneys being much congested and the right showing evidence of previous suppurative nephritis.

Leopold Hudson, whose overflowing energy, together with his ability and industry, are exemplified in the bare record of his life, was one of those whose nature might perhaps be best expressed by the old-fashioned term "winsome." It was impossible for those who knew him to refrain from liking him, and no one could feel surprised at the affection he gained wherever he went. He was always genial and buoyant, retaining the fresh qualities of youth in his years of maturity. It is no wonder that he was popular with students, for he seemed always to thoroughly identify himself with their modes of thought and feeling. Doubtless those who thus came under his influence will remember him as much for the interest he took in their pursuits and pleasures as for the assistance he rendered them in their work. Amongst his other characteristics may be mentioned his optimistic view of life and his versatility in his own spheres of activity. For he had in him something of that enthusiastic spirit, rare enough in this sober-minded world, which carries its possessor through many a difficulty and enables him to undertake with cheerful confidence and zeal many a new duty for the mere pleasure of its opening up fresh avenues and interests. His, too, was a generous nature. The writer of these lines has known him first as a pupil, then as a friend and colleague, and cannot recall his ever saying an unkind word, nor did he seem ever to harbour an unkind thought of anyone. His path through life was therefore freed by his very nature from obstacles that to many seem insurmountable. He had, too, the satisfaction of securing a position which he had thoroughly earned—a position that would, had he lived, have been doubtless justified by the production of original work. The time and opportunity had arrived when this might soon have been expected of him; but he has died like one in view of a land he was not permitted to enter. But if therefore his name had not become as widely known as it surely would have been had life been spared him, yet with those who did know him there will rest no memories but those which are pleasant impressions of a bright, happy, and enthusiastic nature.

A portion of the Burial Office was said in the Church of St. Paul, Great Portland-street, on Thursday, April 1st. The coffin, covered with a purple pall, was placed in the middle of the nave, and the office was said by the Rev. F. J. Brindley, a former chaplain to the Middlesex Hospital, while a body of nurses took the place of a choir. A large number of colleagues and friends of the deceased were present, including (amongst others, for the list is necessarily imperfect) Sir Ralph Thompson (chairman of the Middlesex Hospital), Dr. Cayley, Dr. Colman, Dr. Coupland, Mr. A. Clark, Dr. W. Duncan, Mr. Pearce Gould, Dr. F. J. Hawkins, Mr. Henry Morris, Mr. Edmund Owen, Dr. W. Pasteur, Dr. E. Semple, Mr. W. G. Spencer, Mr. Stonham, Dr. A. Voelcker, Dr. Wethered, Dr. Essex Wynter, and Mr. Thomas Wakley, jun., representing the Editors, and Dr. Cholmeley the staff, of THE LANCET. There were also present many members of the Middlesex Yeomanry and a large contingent of students. At the conclusion of the service the body was removed to Woking for cremation.

EDWARD BOWLES CROWFOOT, M.B. LOND., M.R.C.S. ENG., L.S.A.

A PRACTITIONER of a most worthy type has passed away in the person of Edward B. Crowfoot, of Beccles, Suffolk, youngest son of the late W. E. Crowfoot, F.R.C.P., of Beccles. He was born on Oct. 21st, 1845, and was educated at Fauconberge School, Beccles, and afterwards at Uppingham. He received his medical education at St. Bartholomew's Hospital, of which he was house surgeon in 1869. He obtained the diplomas of M.R.C.S. Eng. and L.S.A. in 1867, and the M.B. degree at the London University in 1868. He joined his father and brother in practice at Beccles in 1870, and was at once appointed medical officer to the Beccles district of the Wangford Union, a post which he held until his death on Feb. 13th, 1897. He was also medical officer of health of the borough of Beccles and surgeon to the Beccles Hospital. He was a hard-working, conscientious man, ever ready to give his services to rich and poor alike, deeply interested in his profession, and of a quiet and retiring manner. The funeral took place on Feb. 17th, and was largely attended by all classes anxious to show respect to one whom they loved and honoured, a true and real friend to all who knew him.

Medical News.

THE VICTORIA UNIVERSITY: FACULTY OF MEDICINE.—At examinations in March the following candidates were successful in the subjects indicated:—

FINAL EXAMINATION.

Part I.—E. L. Anderson, University College; W. J. S. Bythell H. M. Cockcroft, Herbert Davies, J. E. Healey, and W. A. Helm, Owens College; R. B. Jones, University College; Robert Kelsall and James Kemp, Owens College; F. T. A. Lovegrove and H. A. Mawdsley, University College; John Milne, Thomas O'Neill, William Sankey, J. H. Sheldon, and A. T. Sissons, Owens College; Harry Stansfield and Joshua Williamson, Yorkshire College; and D. S. Wylie, Owens College.

Part II.—H. S. H. Callum, Yorkshire College; †Harold Coates, *J. S. Dockray, O. B. Goldschmidt, †Harry Hamer, W. F. Jackson, and †K. H. Jones, Owens College; G. G. Lawson, University College; Henry Mackennal, Owens College; F. E. Marshall, University College; †A. B. Smallman, Owens College; †J. E. Smith, University College; †F. E. Taylor, Yorkshire College; and H. C. Woodhouse and William Wright, Owens College.

* Awarded First-class Honours.
† Awarded Second-class Honours.

SECOND EXAMINATION.

Anatomy and Physiology.—G. P. Alderson, University College; T. P. Allen, Owens College; W. J. W. Anderson and J. D. Andrews, Yorkshire College; W. E. Bamber and H. N. Bridge, Owens College; W. H. Broad and P. A. Browne, University College; A. H. Capamagian, Owens College; Godfrey Carter, Yorkshire College; *Walter Crabtree and C. H. Dawson, Owens College; S. S. Depree and R. J. Ewart, University College; T. L. Fennell, Owens College; C. H. Ferguson, University College; A. E. Finney, Charles Garner, and Archer Greenwood, Owens College; C. H. Greenwood, Yorkshire College; I. W. Hall and E. F. Hill, Owens College; H. C. R. Hime, A. E. Horsfall, and C. E. Horsfall, Yorkshire College; S. K. Hutton, Owens College; W. A. Illingworth and F. W. Johnson, Yorkshire College; L. R. Lempriere, Owens College; Hugh Lett, Yorkshire College; S. F. Linton, University College; C. J. N. Longridge, Owen's College; J. W. Miller, University College; W. H. Morrison and Armitage Morton, Yorkshire College; R. A. Needham, Owens College; A. S. Parkinson, Yorkshire College; A. E. Rayner, C. E. Silvester, Harry Slater, and Herbert Terry, Owens College; T. J. Thomas, University College; A. R. Thompson, Yorkshire College; Harry West, University College; and J. D. Windle and P. R. Wrigley, Owens College.

Materia Medica and Pharmacy.—J. W. Aldred, Owens College; H. M. Birkett, Yorkshire College; *Walter Crabtree, Owens College; S. S. Depree, University College; T. L. Fennell, R. F. Ferris, F. H. Flack, J. P. Good, E. F. Hill, H. S. McLellan, B. C. Middleton, and R. F. Moore, Owens College; W. H. Morrison, Yorkshire College; William Parker, J. H. Stephens, and J. W. Watson, Owens College; Harry West, University College; S. C. Wilkinson, Yorkshire College; and Ernest Young, Owens College.

* Awarded the University Scholarship in Medicine.

UNIVERSITY OF ST. ANDREWS.—The following registered medical practitioners, having passed the required examinations, had the degree of Doctor of Medicine conferred upon them on March 26th, 1897:—

Bunn, Charles Grinling, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A Lond., London.
Buxton, Edward, M.R.C.S. Eng., F.R.C.S. Edin., M.R.C.P. Edin., D.P.H., Liverpool.
Dixon, Thomas Arthur, M.R.C.S. Eng., L.R.C.P. Edin., Surgeon-Major Army Medical Department.
Garstang, Edward Morton, M.R.C.S. Eng., L.R.C.P. Edin., Bolton.
Hadwen, Walter Robert, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., Gloucester.
Hoffman, Arthur Herbert, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S Glasg., London.
Jackson, Thomas William, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond., Chorley.
Mallagh, Alexander, L.R.C.P. Edin., L.R.C.S. Edin., Barrow-in-Furness.
Williams, Howell, M.R.C.S. Eng., L.R.C.P. Edin., Richmond, Yorks.
Williams, Roland Philip, L.R.C.P. Edin., L.R.C.S. Edin., D.P.H., Holyhead.

AT the annual meeting of the Sanitary Institute, held on March 24th, H.R.H. the Duke of Cambridge, K.G., was re-elected President. Professor W. H. Corfield, M.A., M.D. Oxon., F.R.C.P. Lond., and Mr. Thomas Salt were elected Vice-Presidents to fill the vacancies caused by the deaths of Sir George M. Humphry of Cambridge and Sir J. Russell Reynolds, late President of the Royal College of Physicians of London. The report of the Council on the year's work was read.

Hosted by Google

BATH RURAL DISTRICT.—Mr. Charles Harper, medical officer of health for Bath Rural District, has just issued his annual report for 1896. The population of the nineteen parishes of the union, estimated to the middle of 1896, was 24,652. There were 304 deaths during the year, equal to a death-rate of 12·33 per 1000, which was the lowest death-rate recorded for the last five years. The births during the year were 750, giving a birth-rate of 30·42 per 1000.

THE INSPECTION OF MEAT AT CARDIFF.—At their meeting on March 8th the Cardiff Town Council, acting upon the report of the health and port sanitary committee, appointed Mr. Charles Moir, veterinary surgeon, to be meat inspector at a salary of £300 per annum. It was stated that it was the intention of the Bute Company to provide abattoirs together with refrigerators for the carcases. Mr. Moir will devote the whole of his time to the duties of the office.

LUNATIC ASYLUMS IN DORSETSHIRE.—At the March quarterly meeting of the Dorsetshire County Council the chairman of the asylums committee announced that there had been a profit of £580 on the working of the new lunatic asylums for the quarter, and it was hoped that a profit of more than £1200 would be handed over to the finance committee at the end of the six months. There were 710 patients in the asylum, and the maintenance rate was 8*s*. 9*d*. per week.

EMPLOYERS' LIABILITY IN SEWERAGE WORK.—At the Aldershot county court on March 17th his honour Judge Lushington, Q.C., gave a verdict for a widow and her two children for £178 15*s*. in a claim arising out of an accident which occurred on some sewerage work. It appeared that a firm of contractors had to remove a drain near the Royal Artillery Barracks. This drain lay at a depth of 15 ft., and one of the labourers working at that depth was buried alive. The trench was only shored for 5 ft., and that, it was alleged, imperfectly; the remaining 10 ft., in sandy and "made" soil, was said to be quite unprotected.

MEATH HOME FOR EPILEPTICS.—The fourth annual report of the Meath Home of Comfort for Epileptic Women and Girls at Godalming states that the work of the institution was carried on quite satisfactorily during 1896. There were fifteen new admissions and twelve of the inmates left. The committee deplore the loss which the home sustained by the death of Sir J. Russell Reynolds, who was one of its firmest friends, and they make an urgent appeal for increased support, as the subscriptions and donations during the year only amounted to £161 4*s*. The Countess of Meath, who founded the home, has transferred the ownership to four trustees, she herself being one of them.

BRISTOL NURSES' TRAINING INSTITUTION.—The annual meeting of the Bristol Nurses' Training Institution was held on March 16th. The report stated that there were forty nurses on the staff during the past year, and that they did 1188 weeks' work on 451 cases, of which 257 were in Bristol, Clifton, and the immediate neighbourhood. Nine pupils were in training, six of them on a three years' course. The nurses' earnings amounted to £2204. Financially the institution was prosperous, notwithstanding the heavy outlay necessary to start so many pupils on a three years' course; in fact, there was a favourable balance of £82. During 1896 the subscriptions amounted to only £16, so that the institution was practically self-supporting.

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—The annual meeting of the Bristol Hospital for Sick Children and Women was held on March 20th, under the presidency of the Duke of Beaufort. The report stated that 786 children had been treated as in-patients; of these, 74 were in the hospital on Jan. 1st, and 712 new cases have been admitted during the year; the number of women in-patients has been 33, whilst 1135 women and 2937 children have been treated as out-patients. The expenditure exceeded the income by £478, and the accumulated deficit of successive years amounted to £668, of which a sum of £260 was in the balance of the Convalescent Home expenses. At the end of the meeting the President of the hospital presented Miss Combe with a silver teapot and a purse of fifty guineas subscribed by the committee, and a leather bag from the nursing staff. He referred to the fifteen years' faithful service Miss Combe had rendered in the position of matron, and regretted her retirement.

MR. A. A. C. SWINTON will read a paper on Recent Investigations Relating to x Ray Work at the Camera Club on the evening of April 12th. In addition to numerous experimental tubes, some of which will be shown in action, Mr. Swinton will exhibit a new and improved form of Crookes's tube that he has designed, which has an adjustment whereby, without altering the vacuum, the penetrative value of the x rays can be varied at will.

BRISTOL ROYAL INFIRMARY.—The annual meeting of the Bristol Royal Infirmary was held on March 23rd, under the presidency of Sir Charles Cave. The report showed that in 1896, as compared with 1895, there was an increase of 107 in-patients, 678 out-patients, and of 10,026 out-patients' attendances, the totals for 1896 being as follows: In-patients, 3210; out-patients, 34,107; and out-patients' attendances, 65,771. The ordinary income had fallen short of the expenditure, the debt was now increased to £9651, and the chairman stated that unless the subscriptions were increased the committee would have to consider the desirability of either closing two or three of the wards or selling some of their investments. He also remarked that the establishment of a convalescent home in connexion with the hospital and infirmary had the committee's hearty approval, but he hoped that it would not interfere with the subscriptions of the older charitable institutions. In the course of his address the chairman said: "There was no doubt that during the past few years there had been a tendency amongst those who subscribed to look upon their subscriptions as a sort of insurance rather than as an absolute free gift to the charity, and the consequence was that in some cases the infirmary and its benefits had been claimed by those who could not be called poor or destitute individuals. This was to the manifest disadvantage of the infirmary, for they were often pressed for room, especially in the out-patient department, and if those who could afford to pay for their medicines and medical help at home came there and crowded out those who were really poor and destitute the infirmary was not doing the work it was intended to do."

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The annual general meeting was held at the Inns of Court Hotel on March 27th. Mr. W. E. Boulter (Woolwich) was elected President for the ensuing year, Dr. M. M. Bowlan (St. George-in-the-East) secretary, and Dr. F. S. Toogood (Lewisham) treasurer. Mr. H. C. Harris was elected an honorary member. At the dinner which followed Mr. Walter Burney proposed "The Medical Superintendents' Society," and referred to its formation in 1887 and the great work it had performed in binding the members together for their mutual good. Mr. D. M. Forbes (Shoreditch) responded, and said that in his thirty years of experience as a medical superintendent there had been a gradual improvement in the administration of infirmaries, until at the present time they were patterns of good management and economy, and served as examples of what well ordered hospitals should be. These good results had been effected by having medical men as the responsible heads of these institutions, whose special knowledge in hospital construction and management had been of the greatest possible assistance to the designers of the hospitals. Mr. Forbes maintained that it was to the infirmaries that science was indebted for the great advance in hospital construction, while general hospitals being under lay control were very far behind the times. The toast of the retiring officers was responded to by Dr. Toogood, who spoke of the attempts which were being made by a well-known section of noisy female agitators to capture the management of their institutions. The noise appeared to have frightened, or the sex to have captivated, some of the higher local government officials. THE LANCET, he was proud to say, had always supported the supremacy of the medical superintendents.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Registration Bill.

THE order for the second reading of the Midwives Registration Bill was reached after midnight on the Thursday, March 25th, sitting of the House of Commons, but objection was taken to it, and in accordance with the rules of procedure the order was postponed.

Hosted by Google

Infant Life Protection Bill.

The House of Lords on Monday, March 29th, gave a second reading to the Bill for the better protection of infant life, introduced by the Earl of Denbigh at the instance of the London County Council Speaking generally, the Bill follows the recommendations of the Committee of last session; but in the course of debate Lord Denbigh made it known that he will be ready to accept any amendments calculated to make the measure more workable.

Metropolitan Poor-law Children.

When, on Friday, March 26th, the Government asked for a vote on account for the Civil Services, there was a long debate on the proposal of the Local Government Board to set up a new authority for the care of certain classes of pauper children in London.—Sir Albert Rollit, who introduced the subject, argued that this scheme for taking care of the sick, feeble, and imbecile children would mean the creation of a new central board, the building of new institutions, special hospitals, seaside convalescent homes, and the enlistment of an army of new inspectors, all of which must be very costly; and he asked why should not the work be allowed to proceed on the old lines, with the coöperation of the guardians and under the supervision of the Local Government Board.—Sir Walter Foster took the view that as boards of guardians had improved very much in recent years they should, instead of having responsibilities withdrawn from them, be encouraged to go on with their improvements. He suggested that there should be a sub-department of the Local Government Board charged with the care of children, sick as well as healthy, which would be able to do a great deal not only for the education of the children, but also in the way of stamping out those diseases which had been a scandal to Poor-law administration.—Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, pointed out that a departmental committee was now inquiring into the re-organisation of the Local Government Board, and said he was certain that valuable results would follow its report.—Mr. Samuel Smith spoke in praise of the boarding-out system in vogue in Scotland.—Mr. Chaplin, President of the Local Government Board, replying to these and other speeches, said he had elected to proceed by order instead of by legislation for the reason that he was afraid that, in the present condition of public business in the House of Commons, if he relied upon legislation in all probability he would never have had an opportunity this session of dealing effectively with the question at all. He admitted that this method of procedure had its disadvantages. In the absence of opportunities to receive Parliamentary criticism he thought it right to issue this order in a tentative form and send it to all the boards of guardians and managers of districts chiefly concerned to give them an opportunity of making any criticisms they pleased. He believed it had been done with good results. The order had been carefully considered by the local authorities at a conference attended by delegates from every board of guardians concerned, and he had received more than one deputation on the subject. He had now little doubt that, in the final form in which he proposed that the order should be issued, it would command the support of the large majority of the local authorities concerned. He would point out that the great distinction between the recommendations of the report of the committee and the order of the Local Government Board consisted in this, that the committee recommended that a central body should be appointed to take over the charge and control of all the Poor-law children in all the Poor-law institutions in the metropolis, while the order contemplated the appointment of a central authority which was to take over the control of certain classes only of these children. The classes which they proposed should be handed over to the new authority were children suffering from ophthalmia and diseases of the eyes, from skin and scalp diseases, or from mental or physical infirmity, and children requiring the benefits of sea air and in homes for convalescents. His sympathies were entirely with those who disliked the barrack schools, and the policy of the Local Government Board had been for a long time to reduce them wherever possible. The transfer under the order of the classes of children he had named to the new authority was the first step towards facilitating changes in the size, and to some extent the very construction, of those great schools to which so much objection was taken. Very shortly after this report was published the Local Government Board instituted an inquiry by a very able expert (Professor Shaw) into the cubic space and ventilation in these barrack schools. He understood that this gentleman's investigations had been most careful and elaborate, and if the report which he was preparing was to the effect that the cubic space and the ventilation were inadequate, that would at once necessitate the reduction, and probably the very large reduction, of the number of inmates of these schools, and this would afford opportunities for possible alterations in their construction. He had been blamed because his proposals were opposed to the recommendations of the departmental committee; but he could not find in the report of the committee the slightest guidance as to what form the authority was to take, and he was therefore thrown entirely upon his own resources in devising the authority. However, in deference to the views of the committee, he had thought it right in the first instance to propose an entirely new authority instead of the present body, and so he issued an order in that form; but it was evident from the great number of objections the order evoked that there was a large preponderance of opinion in favour of the Metropolitan Asylums Board being made the authority, as against the creation of a new authority. He therefore willingly reconsidered the position. He thought the suggestion that the Metropolitan Asylums Board should be the authority was the best—first, because it avoided the difficulties and expense of creating a new authority; and, secondly, because the Metropolitan Asylums Board afforded in the Exmouth training ship, which was under its charge, the one conspicuous instance of success in the management of Poor-law children. He owned that at first he had some doubts as to whether the Metropolitan Asylums Board, with its numerous duties, would be able to undertake additional responsibilities; but after a series of communications with that body and interviews with its chairman it appeared to him that with some addition to its members it would be perfectly within its scope and capacity to undertake these new duties, and if it appeared to him that it was desired that that should be the final form the order should take, he would not hesitate to adopt a recommendation which had been made to him from many quarters.—Mr. Mundella, who was the next speaker, congratulated Mr. Chaplin on his decision, and after one or two more speeches the debate was brought to a close.

HOUSE OF COMMONS.

THURSDAY, MARCH 25TH.

Rabies in London.

Dr. Farquharson asked the President of the Board of Agriculture on what evidence the cases of canine hydrophobia recently reported in the metropolitan district were diagnosed; how often was the certifying surgeon able to base his conclusions on (1) symptoms observed during life, and (2) an examination of the nervous centres of the suspected dog by the scientific methods practised at the Brown Institute; and whether the department would in future require precise scientific detail before a dog is pronounced to be mad.—Mr. Walter Long replied that ten cases of rabies were reported in the metropolitan district during the first two months of the present year. In every case a post-mortem examination was conducted by the veterinary inspector of the local authority, whilst in two of the cases the dogs were seen alive by veterinary surgeons, and in two others inoculation experiments were made at the Brown Institute. It was essential that the declaration of disease should continue to be made by the veterinary inspector of the local authority as contemplated by the Act, but it was proposed that in each case a full report should be made by that officer for the information of the veterinary advisers of the Board of Agriculture.

The Medical Staff in Scotch Prisons.

Mr. Orr-Ewing asked the Chancellor of the Exchequer whether, in view of the fact that the salaries of Prison Commissioners and prison warders in Scotland and England had been conformed to the same rate of pay, he could state the reason why those of the chaplains and medical officers were not so conformed, the fact of a discrepancy unfavourable to Scotland having been pointed out by them to the Commissioners and the Secretary for Scotland.—Mr. Hanbury, Secretary to the Treasury, replied to the question, saying that the hon. member was wrong in his premiss; the salaries of the Prison Commissioners were not the same, nor were those of the prison warders. Without admitting that the pay should be the same when the circumstances were different, the Treasury had expressed its readiness to consider a redistribution of emoluments in the case of medical officers.—Mr. Orr-Ewing asked the hon. member whether, in view of the fact that the Estimates for the year contained no proposal to increase the salary of any superior officer in the Scottish prison service, he would explain to the House why the recommendations of the Secretary for Scotland on this subject had not received favourable consideration at the hands of the Treasury.—Mr. Hanbury said he did not know how the hon. member became aware of the confidential communications between the Scotch Office and the Treasury referred to in this question. The Secretary for Scotland made six proposals. Four of these were approved in full. One was approved in part; the Treasury gave the two extra medical men he asked for and made a suggestion as to re-arranging the salaries of the medical staff generally, instead of increasing the salaries of two in particular. The sixth request, that for increased pay to chaplains, was refused on the ground that it was not necessary.

Food Products Adulteration.

Mr. Jeffreys asked the First Lord of the Treasury whether his attention had been called to the evidence given by the influential deputation from the Central and Associated Chambers of Agriculture and other representative bodies, received by the President of the Board of Agriculture on March 2nd, that a Bill to give effect to the recommendations of the Select Committee on Food Products Adulteration would receive general support from all quarters of the House; and whether, under these circumstances, the Government would introduce and press forward such a measure in the present session.—Sir John Leng asked the right hon. gentleman whether he was aware that in large cities like London, Manchester, Birmingham, and Glasgow much objection was taken to a recommendation of the Committee on Food Products Adulteration directed against the free sale of a wholesome and nutritious article of food much used by the working classes; and whether, seeing that this recommendation was carried by a majority against the chairman of the Committee, who had described it in the House as of a highly contentious character, and in view of the numerous measures promised in Her Majesty's gracious Speech, he would defer the introduction of another Bill which would be keenly contested both in and out of Parliament.—Mr. Channing asked the right hon. gentleman whether he was aware that the deputation had the warmest support of members on both sides of the House.—Mr. Balfour said, in reply, that it was evident that the support which would be given to a measure of this kind would not at all events be universal. He could not at this moment make any promise as to the introduction or passage of such a Bill, but he would consult with the President of the Board of Agriculture as to whether in any case it might not be

Hosted by Google

desirable to bring in a Bill and read it for the first time, in order that the public might be able to judge of the character of the provisions which in the opinion of the Board of Agriculture it was desirable to introduce.

Clothing for the Army.

Mr. Powell Williams, Financial Secretary to the War Office, stated, in reply to a question by Captain Norton, that after March 31st the practice of giving out work to be executed in the workers' homes would be discontinued. This practice had been found to be very objectionable. The work was often done under conditions which were insanitary and which involved a liability to infection on the part both of the troops and of the workpeople at the clothing factory, while strong suspicion existed of sub-letting on terms which amounted to sweating. The number of people affected was forty-four women and three men. Some of the women were widows of soldiers. None of the work taken from these people would be given to sweating contractors, nor were any sweating contractors allowed to take War Office contracts. The work hitherto given out would be done in the factory, and all the workers in question who were under sixty-five years of age—(viz., thirty-six women and two men) would have the option of coming into the factory. Those who did not avail themselves of the option, or were over sixty-five, would receive a gratuity.

FRIDAY, MARCH 26TH.

The Death of Captain Byrne.

Sir John Colomb asked the First Lord of the Admiralty whether Captain Byrne, Royal Marine Light Infantry (since dead), was brought from Portsmouth to be treated at St. Thomas's Hospital for gunshot wounds received in action at Benin, because the Royal Naval Hospital, Haslar, was not supplied with the necessary apparatus for examination by the Roentgen rays; and if he would take the necessary steps to cause the chief naval hospitals to be furnished with the necessary appliances for the examination of wounds and for the scientific education of the surgeons of the Royal Navy.—Mr. Goschen replied that Captain Byrne, a most able officer, whose death was deeply to be deplored, went to St. Thomas's Hospital for treatment for a gunshot wound at his own request, expressed almost immediately after his arrival on board the hospital ship *Malacca* on Feb. 26th. This wish he reiterated most strongly on his arrival at Portsmouth. It had, so he was informed, no connexion with the question of the examination of his wound by Roentgen ray apparatus. The development of this new science was being closely followed by the naval medical authorities, and care would be taken as assured data were obtained to supply the naval hospitals with all necessary appliances. The naval hospitals were now authorised to have x ray radiographs taken when necessary.

Infectious Disease in Schools.

Lord Hugh Cecil asked the Vice-President of the Committee of Council on Education whether he was aware that the school of St. Stephen's, Lewisham, had suffered a serious temporary diminution of attendance owing to the fear of infectious disease; whether the managers of the school acted in accordance with the regulations of the Department in keeping it open in spite of what was an unreasonable panic; whether, seeing that the school would suffer severely in its grant in consequence, and that, under Article 101 of the Code, had it been closed the period in which it was so closed would not have been reckoned in calculating the attendance, the Education Department could discriminate in favour of a school in this position and allow it the full grant; and whether, if the Department had no such power, they would consider the propriety of applying to Parliament to extend their discretion in the matter.—Sir John Gorst said the facts were as stated, but the Committee of Council had no power to exercise the discretion suggested. The case was very exceptional, and the matter would be considered in connexion with next year's Code.

MONDAY, MARCH 29TH.

Swine Fever.

Admiral Field asked the President of the Board of Agriculture whether his attention had been called to a serious case of swine fever at Bishop's Waltham, on the estate of General Elrington, in November last, where sixty-six pigs of considerable value were ordered to be slaughtered by the local committee in the presence of an inspector acting under the Contagious Diseases (Animals) Act; whether he was aware that fifteen of the carcases were subsequently dressed with a view to being consigned to the Central Meat Market for sale in London, that five of the number were found to be affected with the fever spots and were subsequently buried, and that the remaining ten were nevertheless sent off to London for sale, although they came from the very same pen or stye as those diseased; and whether such action by inspectors was in accordance with the regulations of the Department after the owner had received an official notice that all the pigs in the styes affected were to be slaughtered and buried.—Mr. Walter Long replied that he was aware of the case to which his hon. friend referred, and he had caused full inquiry to be made respecting it. The sixty-seven pigs which were slaughtered by order of one of the Board's inspectors were killed, not because they were diseased, but because they had been exposed to infection, and as a matter of fact, none of them showed any signs of illness. Fifteen of the pigs were found to be fit for the butcher and were dressed accordingly, but on a further examination prior to the consignment of the carcases for sale six of them were found to be somewhat discoloured, and these were accordingly withdrawn and subsequently buried. Discolouration frequently arose from ordinary causes, and there was no evidence whatever that in this case it was due to the presence of swine fever. Under the Board's regulations the most stringent precautions were taken with a view to prevent meat unfit for human food from being consigned for sale, and in the case in question the carcasses sold were examined by a butcher on two successive days and were subsequently passed as sound by the sanitary inspector and the meat salesman on arrival at their destination.

Army Medical Staff.

Captain Norton asked the Under Secretary of State for War what steps he proposed to take in order to fill up the vacancies in, and complete the establishment of, the Army Medical Staff; and whether, in case of mobilisation, the Army Medical Staff was now sufficient for the medical needs of Army corps.—Mr. Brodrick said, in reply, that it was intended to give an increase of pay in India and a shorter tour of service there; assistance in forming medical messes at large stations; quarters in barracks where possible; and better opportunities for study on return from foreign service. One or two other matters affecting the Service were still under consideration. It was hoped that these additional advantages would increase the number of candidates for the Service. His answer to the second part of the question was in the affirmative.

Pleuro-Pneumonia in London.

Mr. Field asked the President of the Board of Agriculture whether another outbreak of pleuro-pneumonia contagiosa had occurred recently in London; whether this further outbreak and the result of investigations had satisfied the authorities that the disease was local and not imported; and whether Ireland had had a clean bill of health for live stock (excepting swine fever) for a much longer period than Great Britain.—Mr. Walter Long replied that it was the case that another outbreak of pleuro-pneumonia had occurred in London. So far as the inquiries of the Board had yet proceeded they had no reason to think that the disease was imported. It was the case that no outbreak of pleuro-pneumonia had been reported in Ireland for a much longer period than in Great Britain.

Disease among the Troops in India.

Lord George Hamilton, replying to a question by Sir James Fergusson, said that for some time past he had been in communication with the Viceroy on this subject, and he proposed to lay on the table of the House a despatch addressed to the Government of India, in which the views of Her Majesty's Government were stated at length.—Major Rasch asked the First Lord of the Treasury whether, in order to dispel misconception on this subject, he would give facilities for its discussion.—Mr. Balfour said he hoped and believed the despatch was of such a character as not to call for any debate in the House.

TUESDAY, MARCH 30TH.

The London Water Question.

Mr. Chaplin announced that the terms of reference to the Royal Commission on the London Water Question are as follows: 1. To inquire and report whether, having regard to financial considerations and to present and prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies, it is desirable, in the interests of the ratepayers and water consumers in those districts, that the undertakings of the water companies should be acquired and managed either (*a*) by one authority, or (*b*) by several authorities, and, if so, what should be such authority or authorities. To what extent physical severance of the works and other property and sources of supply of the several companies, and the division thereof between different local authorities within the limits of supply, are practicable and desirable, and what are the legal powers necessary to give effect to any such arrangements. 2. If the undertakings are not so acquired, whether additional powers of control should be exercised by local or other authorities, and if so what those powers should be. 3. Whether it is practicable to connect any two or more of the different systems of supply now administered by the eight metropolitan companies, and, if so, by whom and in what proportions should the cost of connecting them be borne, and what are the legal powers necessary to give effect to any such arrangement.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARNOLD, E. G. EMERSON, M.B., B.S., has been appointed a Clinical Assistant to the Chelsea Hospital for Women.

BAILEY, T. R., M.D., C.M. Edin., has been appointed Medical Officer for the Fourth Sanitary District of the Wolverhampton Union.

BARNES, E. H., M.B. Syd., has been appointed a Resident Medical Officer to the Sydney Hospital, New South Wales.

BOYAN, JOHN, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Western General Dispensary, Marylebone-road, London.

BRIGHT, R. S., M.R.C.S. Eng., has been appointed a Member of the Central Board of Health, Hobart, Tasmania.

BURKITT, G. O. E., L.R.C.P., L.R.C.S. Irel., D P.H., has been appointed Health Officer at Leaderville, Western Australia.

BURNIE, W. GILCHRIST, M.R.C.S. Eng., L.S.A. Lond., has been appointed Honorary Consulting Medical Officer to the Bradford Children's Hospital.

COLE, F. H., M.B., Ch.B. Melb., has been re-appointed Lecturer on Pharmacy to the Medical Students of the Melbourne University, Victoria, Australia.

DODS, JAS., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer to the Brisbane United Friendly Societies, Queensland.

FOX, J. R., M.B. Melb., has been appointed Officer of Health for Leigh Shire, Victoria, Australia.

GARDINER, JOHN, B.A. Oxon, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Western General Dispensary, Marylebone-road, London.

GRANT, A. S., M.R.C.S., L.R.C.P., has been appointed a Clinical Assistant to the Chelsea Hospital for Women.

HARRIS, DAVID, M.B., M.S. Glasg., has been appointed Medical Officer to the Carmarthen Union and District No. 1.

HARRIS, W. H., M.B. Syd., has been appointed a Resident Medical Officer to the Sydney Hospital, New South Wales.

HARVEY, L. W., L.R.C.P., L.R.C.S. Edin. L.F.P.S. Glasg., has been appointed a Medical Officer to the Grenfell Hospital, New South Wales.

Hosted by Google

HERRIOT, S., L.R.C.P., L.R.C.S. Edin., has been appointed a Surgeon to the Bulong Hospital, Western Australia.
HONNYWILL, ALFRED ORAM, L.R.C.S., L.R.C.P., L.M. Edin., has been appointed Medical Officer to the Sutton District of the London, Brighton, and South Coast Railway Provident Society. Also Medical Referee to the Prudential Assurance Company.
HOPKINS, G. H., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed an Honorary Medical Officer to the Lady Bowen Hospital, Brisbane, Queensland.
ISBESTER, T., M.B. Adel., has been appointed a Resident Medical Officer to the Sydney Hospital, New South Wales.
JOHNSTON, A. A., L.K.Q.C.P. Irel., L.R.C.S. Edin., has been appointed a Public Vaccinator at Clifton Hill, Victoria, Australia.
KRUGER, C. H., M.B., C.M., has been appointed a Clinical Assistant to the Chelsea Hospital for Women.
LEY, G. J., M.B. Melb., has been appointed a Public Vaccinator at Chiltern, Victoria, Australia.
LININGTON, W. W., F.R.C.S. Eng., has been appointed Resident Casualty Officer to the General Infirmary, Leeds.
LYSTER, A. E., M.R.C.S. Eng., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Fourth District of the Chelmsford Union, vice W. Hart, resigned.
MCCALLUM GAVIN, M.B., C.M. Glasg., has been appointed a Resident Surgeon to the Geelong Infirmary and Benevolent Asylum, Victoria, Australia.
MOIR, WM., M.B., Ch. M. Aberd., has been appointed Officer of Health for Mirboo Shire, Victoria, Australia.
PADBURY, G. J., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Hawkchurch Sanitary District of the Axminster Union.
PLOWMAN, S., F.R.C.S. Eng., L.R.C.P. Lond., has been re-appointed a Lecturer on Materia Medica to the College of Pharmacy, Victoria, Australia.
RIMELL, A. T., M.R.C.S. Eng., L.R.C.P. Edin., has been appointed Medical Officer and Public Vaccinator for the Tydd, Sutton St. James, and Long Sutton Districts of the Holbeach Union.
RUDALL, J. F., M.B., Ch.B. Melb., M.R.C.S. Eng., has been appointed Officer of Health for South Gippsland Shire, Victoria, Australia.
SCOTT, C. H., M.B., Ch. M. Syd., has been re-appointed Medical Officer for the Bourke Hospital, New South Wales.
SEED, WM. P., L.R.C.P. Lond., M.R.C.S., has been appointed a Resident Physician to the Coolgardie Hospital, Western Australia.
SMITH, J. W., M.B. Edin., F.R.C.S. Eng., has been appointed Honorary Anæsthetist to the Victoria Dental Hospital, Manchester.
TAYLOR, E. CLAUDE, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Deputy Assistant Surgeon to the London Temperance Hospital.
TERRY, H., M.B. Syd., has been appointed a Resident Medical Officer to the Sydney Hospital, New South Wales.
THOMPSON, W. H., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the Bradford Children's Hospital.
TIDSWELL, F., M.B., Ch.M Syd., D.P.H. Cantab., has been appointed a Demonstrator of Physiology to the Sydney University, New South Wales.
TILLEY, HERBERT, M.D., B.S. Lond., has been appointed Surgeon to the London Throat Hospital, Great Portland-street, for Diseases of the Ear, Throat and Nose.
TOTHILL, F. C., M.B., C.M. Edin., has been appointed Medical Officer for the Ashford Sanitary District of the Staines Union.
WARD, HOWARD P., M.B. Lond., M.R.C.S. Eng., L.S.A., has been appointed Assistant Physician to the Royal South Hants Infirmary, Southampton.
WATT, GEO., M.B., Ch.M. Aberd., has been appointed a Medical Officer for the Narrandera Hospital, New South Wales.
WATSON, A. E. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Destitute Poor and Aborigines in the District of Port Germein, South Australia.
WESTMACOTT, F. H., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Victoria Dental Hospital, Manchester.
WILLIAMSON, OLIVER K., M.B., has been appointed Junior Resident Medical Officer and Registrar to the Evelina Hospital for Sick Children, Southwark Bridge-road, London, S.E.
WILLMOT, ROBT., F.R.C.S. Edin., M.R.C.S. Eng., has been appointed an Official Visitor to the Hospital for the Insane, New Norfolk, Australia.
WRIGHT, THOS. N., L.R.C.P. Lond., M.R.C.S., has been appointed a Government Medical Officer and Vaccinator for the Police District of Port Stephens, New South Wales.
WRIGLEY, F. H., L.R.C.S. Edin., has been re-appointed a Medical Officer to the Glen Innes Hospital, New South Wales.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon Salary £100 per annum, with rooms and attendance (not board).
COTFORD ASYLUM, near Taunton, Somerset.—Assistant Medical Officer, unmarried. Salary £120, with annual rise of £10 to £150, furnished apartments, board, attendance, and washing.
GENERAL INFIRMARY, Leeds.—Resident Surgical Officer. Salary £100 per annum, with board, residence, and washing.
GERMAN HOSPITAL, Dalston, N.E.—Honorary Ophthalmic Surgeon.
GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six months. Board, lodging, and washing in hospital provided.
HANTS COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance. Applications to the Committee of Visitors, Knowle, Fareham.
HOSPITAL FOR WOMEN AND CHILDREN, Leeds.—House Surgeon for twelve months. Salary £90 per annum.
LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES.—Honorary Assistant Surgeon.
METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Dental Surgeon.
MIDDLESEX HOSPITAL, W.—Assistant Surgeon. Also Aural Surgeon.
NEW SOUTH WALES.—Bacteriologist and Assistant to the President of the Board of Health of the Colony. Salary £600 per annum. Applications to Agent-General for New South Wales, 9, Victoria-street, London, S.W.
ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Board, lodging, and washing provided.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Pathological Curator of the Museum.
ST. SAVIOUR'S UNION, Surrey.—Medical Superintendent at the Infirmary, East Dulwich-grove, S.E. Salary at the rate of £400 per annum, with unfurnished house, coals, gas, and water. An annual percentage deduction from the salary and emoluments will be made according to the Poor-law Officers Superannuation Act, 1896. Applications to the Clerk, Union Offices John-street, West, Blackfriars-road, S.E.
SHEFFIELD UNION WORKHOUSE INFIRMARY.—Junior Assistant Medical Officer, unmarried, at the Workhouse Infirmary, Fir Vale, Sheffield, for six months. An honorarium of £12 will be granted, and furnished apartments, board, and washing provided. Applications to Clerk to the Guardians, Union Offices, West Bar, Sheffield.
SWANSEA GENERAL HOSPITAL.—House Physician for one year. Salary £50 per annum, with board, apartments, laundress, and attendance.
VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £80 per annum, rising to £100, with board, residence, and washing.
WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the hospital. Salary £80 per annum, with board, lodging, and washing.
WOLVERHAMPTON EYE INFIRMARY.—House Surgeon, for six months. Salary at the rate of £70 per annum, with rooms, board, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ARCHER.—On March 26th, at Hillfield-road, West Hampstead, the wife of Stafford L. Archer, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.
BREESE.—On March 24th, at Kennington-park-road, the wife of F. Breese, L.D.S., of a son.
CARLIER.—On March 26th, at Morningside-drive, Edinburgh, the wife of E. Wace Carlier, M.D., B.Sc., &c., of a daughter.
ECCLES.—On March 25th, at Harley-street, W., the wife of W. McAdam Eccles, M.S., F.R.C.S., of a son.
FORD.—On March 25th, at Kent-road, Southsea, the wife of Vernon Ford, Surgeon, of a daughter, stillborn.
OVEREND.—On March 19th, at Montgomery-terrace-road, Sheffield, the wife of Wilkinson Overend, B.A., M.B. Oxon., of a daughter.
RUSSELL.—On March 24th, at Plas tan Altran, Holyhead, the wife of William Fox Russell, M.B., of a son.
WILSON.—On March 25th, at Sydney House, Blackrock, County Dublin, the wife of S. Wesley Wilson, Physician and Surgeon, of a son.

MARRIAGES.

CRAWFORD—CAMPBELL.—On March 25th, at the Catholic Apostolic Church, Dundee, Douglas Crawford, M.B., F.R.C.S., of Liverpool, to Edith Violet, youngest daughter of Walter Campbell, South Tay-street, Dundee.
FORRESTER—HENDERSON.—On March 25th, at Mayfield Free Church, Edinburgh, Harvie Anderson Forrester, M.B., C.M., third son of the late William Forrester, of Arngibbon, Perthshire, to Helen Isabella Rhind, second daughter of the late Frank Henderson, M.P., Dundee.
FULLERTON—WISE.—On March 25th, at St. Peter's, Bournemouth, Robert Fullerton, M.D., of Glasgow, to Lucy Kate Lloyd, elder daughter of William Lloyd Wise, J.P., of Wimbledon and Southend-on-Sea.
ROBINSON—HOPE.—On March 27th, at St. Martin's Church, Guernsey, Clement Sumner Robinson, Surgeon-Captain, A.M.S., h.p., youngest son of the late Rev. C. D. P. Robinson, to Gertrude, fourth daughter of S. T. Hope, of Les Douvres, St. Martin's, Guernsey.

DEATHS.

GUINNESS.—On March 9th, at Selkirk-parade, Cheltenham, Arthur Guinness, M.D., aged 84.
HARRIS.—On March 18th, at Dover, Florence, the beloved wife of Surgeon-Major F. A. Harris, Army Medical Staff.
HICKMAN.—On March 27th, at Harley-street, W., William Hickman, D.L., J.P., F.R.C.S., Surgeon-in-Ordinary to H.R.H. the Duke of Saxe-Coburg-Gotha, in his 61st year.
HOWITT.—On March 29th, Francis Howitt, M.D., of Nottingham, in his 61st year.
HUDSON.—On March 29th, at his residence, Harley-street, W., Charles Elliot Leopold Barton Hudson, F.R.C.S., in his 35th year.
KENT.—On March 26th, at Cardigan-road, Richmond-hill, Thomas John Kent, M.R.C.S., of Piccadilly, in his 74th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (7th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (8th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (10th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (5th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Paper:—Mr. A. H. Smith: The Microscopical Aspect of certain Lesions induced by Dental Caries. A Demonstration of the Use of Choquet's newly-invented Microtome will be given by the reader of the paper.

WEDNESDAY (7th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Targett, Dr. D. Robinson and others. Papers:—Dr. G. F. Blacker: The Treatment of Placenta Prævia by Champetier de Ribes' Bag.—Dr. T. Wilson: Chronic Axial Rotation of an Ovarian Cyst giving rise to Extreme Twisting of the Elongated Uterus.

THURSDAY (8th).—SOCIETY FOR THE STUDY OF INEBRIETY (11, Chandos-street, Cavendish-square, W.)—3 45 P.M. Papers: Dr. C. R. Drysdale: Alcohol in Therapeutics *vs* Inebriety.—Rev. A. K. Cherril: Are Acquired Characters Transmissible?

FRIDAY (9th).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. H. Marsh: A Case of Sarcoma of the Prostate Gland.—Mr. R. Johnson: Multilocular Ovarian Cyst in a Child of five years, Axial Rotation, Ovariotomy.—Mr. W. G. Spencer: Hydatid Cysts removed from the Left Pleura, from behind the Mesentery, and from the Right Lobe of the Liver.—Mr. C. B. Lockwood: A Case of Wound of the Mesentery with subsequent Gangrene of the Intestine.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (5th). — THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Prof. T. R. Smith: Sanitary Building Construction.

TUESDAY (6th).—ROYAL COLLEGE OF PHYSICIANS—5 P.M. Dr. H. C. Bastian: Some Problems in Connexion with Aphasia and other Speech Defects. (Lumleian Lecture.)

LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Moral and Impulsive Insanities, and Lunacy Law.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Lupus Erythematosus.

WEDNESDAY (7th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Dr. Louis Parkes (conducted by): Inspection and Demonstration at the Disinfecting Station, Chelsea. 4 P.M. Inspection of the West London Paper Mill Company's Works, Fallopian Wharf, Lot's-road, Chelsea. 8 P.M. Discussion, opened by Mr. H. R. Kenwood, on Notification of Measles.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Disinfection and Disinfectants.

THURSDAY (8th). — ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. H. C. Bastian: Some Problems in Connexion with Aphasia and other Speech Defects. (Lumleian Lecture.)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. J. W. Clarke: Details of Plumbers' Work.

FRIDAY (9th). — LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Tetanus, Rabies, and Cholera.

SATURDAY (10th). — THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—2.30 P.M. Mr. C. Jones (conducted by): Inspection and Demonstration at the Sewage and Destructor Works, Ealing.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

LIFE ASSURANCE AND PROVISION FOR OLD AGE.

WE have received the prospectus issued by the Acme Insurance Company for "Health, Endowment, and Life Assurance," the life part of which novel combination is to be carried out by the English and Scottish Law Life Association. From the nature of the risks and contingencies which it provides against the company appears to meet the requirements of professional men. Its scheme of operations seems to include some new features devised for the purpose of arriving at an economical method of securing the protection of income during incapacity, a provision for advanced life, and, thirdly, in the event of premature decease, the return of outlay made to secure the first two objects. Table III. provides what really amounts to endowment assurance payable at the age of sixty-five years, the added cost for which shows the rate for this important part of the contract to be far below those usually current. This means of making provision for advanced life at a relatively small outlay will no doubt attract much attention, and the company in its exposition of the details of the scheme claims that it is quite an innovation in assurances of this description. Among the tables is one affording those whose income is not immediately affected by incapacity deferred benefits at reduced rates. It has hitherto been a condition in all benefit societies to insist on rigid confinement to the house as the only evidence of incapacity that would be admitted, and full benefits could be obtained only on these terms, but the Acme Company is willing, on application being made, to relax this regulation so far as to allow a health resort to be visited during convalescence. The company proposes to pay adequate fees for the requisite medical examinations, and stipulates that the admission of any claim shall be conditional on the production of proper certificates from duly qualified medical practitioners. The offices of the Company are at 14, Norfolk-street, Strand, W.C.

THE HOSPITAL OF ST. FRANCIS OF ASSISI.

ST. FRANCIS was undoubtedly one of the world's heroes, but we do not quite see what the proposed hospital to be founded in his name is going to do. According to the prospectus it is to be "A protest of the world against inhumanity. A revolt of the awakening soul against the crushing horrors of vivisection. An aspiration after the Divine gentleness." This is all very well but are the authorities going to eliminate from their methods of treatment all matters that have been discovered by experiments on animals? To be consistent they should do so, and in that case the action of the heart, the circulation of the blood, and many other physiological truths will be still unknown to them. The language of the prospectus is marvellous—thus we are told that the new hospital shall rise "a pure and peaceful temple, with its base amid the sorrows of creation and its lofty minarets within the eternal sympathy of the Creator." Why "minarets"?

H. S.—It is important that the profession should approach the solution of these questions which concern them as a whole in a spirit of conciliation.

THE VALUE OF CREOLIN INHALATION.

To the Editors of THE LANCET.

SIRS,—Inhalations of the vapour given off from boiling creolin have in my hands proved beneficial in bronchial asthma. I use a large test tube about five-eighths of an inch in diameter, and boil some three drachms of creolin in it over an ordinary spirit lamp. The patient sits with his mouth wide open a foot or eighteen inches from the tube and inhales the vapour which comes off, mixed, of course, with air. The inhalation is kept up for from one to ten or fifteen minutes, according to circumstances. I repeat this inhalation daily for a month or six weeks. Obviously the greatest care is required, for it would, I suppose, be possible to suffocate a person if sufficient air were not inspired with the vapour; but I have only once seen any ill effect (and that only temporary) from this treatment. In that case—one of chronic laryngeal catarrh—the patient, who had never before taken the inhalation, almost collapsed after some five minutes of the treatment, but he was quickly restored on removal to the fresh air. In this case, too, the inhalation was repeated daily without any tendency to collapse, and the complaint was completely cured by this treatment. I have found it necessary to observe the following precautions:—(1) The inhalation should *not* be given during a paroxysm of asthma (its effect is on the condition of the lung itself, not, so far as I know, on the paroxysm, just, I imagine, as that of creolin is on the skin in certain cutaneous eruptions); (2) the temperature of the patient should not be above normal; (3) the inhalation should not be administered by an irresponsible person; (4) during the first week of treatment the inhalation should be given for one minute only on each day; (5) should the patient become faint or complain of giddiness the inhalation must be discontinued at once, and the patient removed into the fresh air; and (6) care must be taken that the vapour (which is very inflammable) does not catch fire, and that the liquid does not boil over. In November, 1894, to ascertain if this treatment could be safely adopted, I tried the effect of an inhalation on myself. I have since then treated various affections of the air passages in this way, and have obtained the best results in bronchial asthma.

I am, Sirs, yours faithfully,
Burton-on-Trent. DIGBY F. B. COTES, M.R.C.S.Eng., L.S.A.Lond.

Hypatia.—(1) Messrs. Baird and Tatlock, Cross-street, Hatton-garden; (2) Woodhead's Bacteriology and the handbooks of Kanthack and Drysdale; and (3) Leitz or Zeiss with an oil immersion.

THE CORSET QUESTION.

MADAME GACHES-SARRAUTE, M.D., the deviser of the rational corset, is indefatigable. In THE LANCET, Dec. 5th, 1896, at page 1655, we gave a brief description of the appliance which this lady is endeavouring to render equally acceptable to dressmakers and hygienists, and now we learn that in order to be thoroughly up to date she has enlisted the x rays on behalf of her invention. At a recent meeting of the Académie de Médecine Dr. Laborde exhibited a series of three radiographs, one taken from the nude, another representing a woman wearing a Gaches-Sarraute bodice, and the third the same person constricted by a corset of the ordinary kind. The effect on the learned academicians is said to have been altogether conclusive, but it remains to be seen whether the ladies themselves will be as easily convinced. The desire for a taper waist is so deeply implanted in the female mind that even the startling testimony to the evil consequences of tight lacing thus unexpectedly afforded may prove of little avail.

DUPLICATE MEDICAL PERIODICALS.

To the Editors of THE LANCET.

SIRS,—The Bristol Medical Library has a large number of duplicate periodicals which it will have much pleasure in giving to any library that needs them for completing sets. I am, Sirs, yours truly,

L. M. GRIFFITHS, Hon. Librarian.
Bristol Medical Library, University College, Bristol, March 27th, 1897.

PITY THE POOR MEDICAL OFFICER OF HEALTH.

OUR contemporary, the *Pall Mall Gazette*, in its issue of March 24th, has an amusing article called "The Situation at Sureton-in-the-Mud." Sureton was a little village recently dowered with a parish council and other democratic blessings. The village also rejoiced in the possession of two medical men, of whom the senior was elected "Medical Officer of Health for the Sureton-in-the-Mud division of the Wyck-on-the-Wold Rural District Council." This office though imposing enough in name carried with it duties which, as a rule, do not generally fall to the lot of a medical officer of health, for "the Doctor was at the beck and call, at any hour of the day or night, of any free and independent elector or of any member of the family who might happen to feel indisposed." Not to make too long a story of it, the medical officer began to make rude and officious inquiries into the water-supply, and the authorities of Sureton, though ready enough to root up well-tried and beneficent institutions, naturally objected, and when, after eight years' persistent agitation, the Red Tape Offices exhorted the Sureton authorities to amend their water-supply the said authorities were scandalised. Thereupon a councillor, remembering that the appointment of medical officer of health was an annual one, proposed to oust the holder at the forthcoming election and to elect the other medical man, a new comer, who also chanced to be a friend of his (the councillor). The article proceeds:—

> "The situation was explained to me by an eminent councillor whom I found hanging over the railings on the bridge spanning the Sure, expectorating meditatively into the water. This pursuit seemed to be his chief occupation.
>
> "'No, my young sir, I don't say but what the Doctor 'asn't performed 'is dooties satisfact'ry; I don't say but what 'e is hequal to 'is job (he had been a gold medallist or something of the kind of his University) but what I do say is, that being medical horficer 'e 'as no call to go a-snuffling about the drains for to raise the rates of the parish.'
>
> "'But the outbreak of typhoid?'
>
> "'That's what 'e's there for. If there wasn't no typhoid we shouldn't want no medical horficer, should us? It stands to reason.'
>
> "'I remember his driving over to Wyck, which is beyond his ten-mile radius, and sitting up through that bitter night with Sally Lane. I remember him sending port wine to ——'
>
> "'Now you are trying to come it with the gratitoode game. Why, bless us! You might as well talk about gratitoode to the parson. What is the likes of them paid for?'
>
> "'But if the County Council and the Board in London insist on a water-supply, whether you kick the Doctor out or not it will have to come."
>
> "'I don't say but what that is likely enough. But we can take the title—the happellation—away from the Doctor, and Lawyer Timmins says as 'ow that will play 'ole 'Arry with 'is privit practice. We'll learn him 'ow to come interfering with our water and sending up the rates. Jones 'll know better, however.'"

Mr. J. E. Tuke is thanked for his reply.

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—I have followed the correspondence on this subject in the columns of THE LANCET with deep interest. The principal question your writers ask is which is the best antiseptic. I think the first thing to be decided is, should we in general practice go in for so-called antiseptic midwifery at all? By which I mean the use of the uterine and vaginal douche. For my part, I have attended over 1000 cases in London and only used the douche three times, and have not yet had a fatal case or one of puerperal fever. I never use mercury in any form and only take the precaution of putting my hands and instruments into a hot solution of permanganate of potash before introducing them into the womb. It would be interesting to compare results in general practice of so-called "antiseptic midwifery" with that in which antiseptics take a minor place. I am, Sirs, yours truly,

Tufnell-park-road, N., March 26th, 1897. CHAS. DISNEY ROE.

Mrs. Charlotte E. Field.—The circumstances should be brought to our attention by the consultant.

THE PROTECTION OF BIRDS.

THE Society for the Protection of Birds is a most praiseworthy one; it not only strives to prevent the destruction of birds for the ornamentation of human beings, but also any wanton destruction. There is nothing so annoying as to read in the paper, as we only too often do, "A fine specimen of the now rare bird —— has been shot by ——"—some "sportsman" who ought to know better. Many a bird formerly common in England might be so again if it were not for this insensate custom. The bearded tit is almost extinct, the bustard quite so, and the bittern, the ruff, the rose-coloured pastor, and the golden eagle are hardly ever seen, though the last is not so uncommon as the others. The secretary of the society is Mrs. F. E. Lemon, Hilcrest Redhill, Surrey.

AMERICAN VIEWS OF HOSPITAL AND DISPENSARY ABUSE.

THE abuse of medical charities is becoming as burning a question in New York as it is in London. The *New York Medical Record* of March 6th contains two articles on the subject, one a paper on the Dispensaries of New York, their Use and Abuse, by Walter Brooks Bronner, A.B., M.D., New York. In this paper Dr. Bronner shows that at these institutions 707,058 patients were treated, who made in all 2,026,360 visits, and 1,039,632 prescriptions were filled, for which a fee ranging from ten to twenty-five cents was charged in the vast majority of cases in all the forty-four institutions, excepting those under the Department of Charities and the North-west Dispensary. On a conservative estimate 40 per cent. were able to pay a doctor. Dr. Bronner absolves the people from blame and blames the profession. The subject was also discussed at a special meeting of the New York County Medical Association, where the same views prevailed as to the culpability of the profession, including its heads. One speaker quoted the case of a woman who was advised to give her child fresh air by riding in a ferry boat, and replied that she intended to make a voyage to Europe, which she thought would be better. We hope most of the other statements at this meeting are more reliable than that of Dr. Freudenthal, who said that in London everybody applying at a clinic had to bring a certificate of poverty from his landlord! Our contemporary in a leading article says the situation is a serious one, and that the number of patients treated who are undeserving of charity is simply appalling. What is wanted is organisation and discipline in the profession.

Mr. W. J. Dixon is advised to consult his regular medical attendant.

"BLOOD ERYTHEMA."

To the Editors of THE LANCET.

SIRS,—I notice that the eruption so-named is mentioned and discussed in THE LANCET of March 20th, and the view is there expressed that it is in all probability due to idiosyncrasy on the part of the subject. I have, however, twice noticed this eruption on the back of my own hand and wrist after having washed off dried arterial blood after operations. There are two points which I should like to mention here regarding the etiology of this condition. 1. The fact of its having occurred only on two occasions in my case in the course of about 100 operations seems to favour the view that there must be some peculiarity in the patient's blood, unless the operator is immune at times and not at other times. 2. May not the application of turpentine, corrosive sublimate solution, and other antiseptics possibly act as remote causes of this peculiar condition? I am, Sirs, yours truly,

VINCENT BURROW, M.B., B.S.Durh.

Lancaster-road, W., March 25th, 1897.

Dr. S.—The details which our correspondent gives certainly indicate unprofessional conduct, but we could not comment upon such matters until we knew that no explanation was forthcoming from the other side. Dr. S. may have been misinformed.

A NEW METHOD OF HYSTERECTOMY.

MR. R. HUGH HODGSON suggests a new mode of procedure in cases of hysterectomy in which it is deemed desirable to retain the cervix. His recommendation is based upon experiments performed on the dead body. After having tied the ovarian and uterine arteries and divided the broad ligaments close to the uterus, the peritoneum being saved as much as is deemed necessary for the subsequent stages of the operation, the cervix is cut through about the level of the internal os and ligatures passed through the cut edges of the broad ligaments and peritoneum and left in long loops. Then the cervical canal having been dilated per vaginam, the end of a pair of long forceps is passed up through it into the abdominal cavity, and the loops of the ligatures seized and drawn upon until the edges of the broad ligaments and peritoneum are within the vagina, where they are then packed with iodoform gauze, as is the practice followed by Mr. Bowreman Jessett in his pan-hysterectomies. The advantage of this disposal of the stumps over the usual methods of either sewing the peritoneum together over it, submitting it to the serre-nœud, or stitching it to the abdominal wound, is claimed to be that there is absolutely no raw surface left in the floor of the pelvis, no loop formed between the abdominal wall and the stump, and no abnormal traction on the abdominal wall.

Mr. V. C. Mallard.—The idea is a kindly one.

THE MATERNITY CHARITY AND DISTRICT NURSES' HOME, PLAISTOW, E.

THIS institution does excellent work among the poor of Plaistow and West Ham. The district is on the outskirts of East London, and the population consists almost entirely of the labouring class. The committee of the charity makes an urgent appeal for subscriptions and donations, which may be sent either to the treasurer, Mr. Robert Williams, Howard's-road, Plaistow, E., or to the bankers, Messrs. Williams, Deacon, and Co., 20, Birchin-lane, E.C.

MALE NURSES' (TEMPERANCE) ASSOCIATION.

WE have on various occasions referred to the desirability of employing male nurses in certain cases both of bodily and mental disorder. It is satisfactory to find that this view is extensively adopted, one proof of which is that the Male Nurses' (Temperance) Association is at present finding constant work for nearly 100 men, and that last year each man's average earnings were £101 18s. after paying all expenses. A large number of the nurses and travelling attendants are fulfilling engagements on the Continent, and in America, India, the Colonies, Egypt, and South Africa. The offices of the association are at 10, Thayer-street, Manchester-square, W.

Mr. Clement H. Sers.—We regret that pressure on our space makes it absolutely impossible for us to publish so long a communication.

"THE DOSE OF IPECACUANHA."

To the Editors of THE LANCET.

SIRS,—Referring to my letter published in THE LANCET of March 13th, wherein I stated that I had steadily taken six times the customary dose of ipecacuanha wine without perceptible effect of any kind, I have since been informed by more than one leading pharmacist that it has for long been known to pharmacists that the process now directed in the British Pharmacopœia for preparing ipecacuanha wine is bad. They say that the alkaloids extracted by an acetic menstruum are destroyed by being heated with that menstruum on evaporation. This, they say, is the cause of the inactivity of the present official preparation. The result I obtained clinically has therefore for long been ascertained pharmaceutically.

It seems that the favourite remedy for the most widely fatal disease in this country is practically inert. In the dose in which it is commonly prescribed it is absolutely inert, provided it be prepared in the only manner in which the Medical Council permits it to be prepared.

I am, Sirs, obediently yours,

BALMANNO SQUIRE.

Weymouth-street, Portland-place, W., March 22nd, 1897.

To the Editors of THE LANCET.

SIRS,—Dr. Balmanno Squire's letter on the above subject in THE LANCET of March 13th brings forward in medical literature a point which has been the subject of no little investigation in pharmacy. In a paper (*Pharmaceutical Journal*, 3, xx., p. 254) it was shown that following the process of the British Pharmacopœia, 1885, a considerable proportion (nearly a quarter) of alkaloids present in the root, though completely extracted by the acetic solvent, was destroyed by subsequent treatment—viz., evaporation to dryness before solution in sherry. It was shown that the process of the British Pharmacopœia, 1867, from the point of view of alkaloidal content and medicinal activity, was superior to that of the 1885 edition. In the paper referred to a process was detailed for the preparation of a standardised liquid extract of ipecacuanha, from which, by simple dilution with sherry, a wine of constant alkaloidal content could be obtained, and it is found that a dose of five minims of this wine has marked expectorant effect. The advantages of this standardised liquid extract and wine have been so widely recognised and its use so generally adopted that it must unquestionably have come under the notice of those who have charge of the compilation of the new British Pharmacopœia.

I am, Sirs, yours truly,

March 23rd, 1897. JOHN C. UMNEY.

Dr. John Love's communication will receive attention.

THE MILK STERILISING APPARATUS OF DR. POPP AND DR. BECKER.

A CORRESPONDENT writes:—"I shall be glad if any of your readers can inform me where I might get some independent opinion with regard to the apparatus invented by Dr. Popp and Dr. Becker for sterilising milk."

During the week marked copies of the following newspapers have been received:—*Essex County Standard, Hull News, Norfolk Chronicle, Wolverhampton Chronicle, Wigan Observer, Southampton Times, Lowestoft Standard, Times of India, Kidderminster Shuttle, Pioneer Mail, Manchester Guardian, Folkestone Express, Rochester Journal, South Wales Daily News, Bradford Observer, Builder, Sussex Daily News, Walsall Advertiser, Hastings News, Liverpool Daily Post, Newcastle Chronicle, Derbyshire Times, Bedford Standard, Lichfield Mercury, Worcestershire Chronicle, Oban Times, Western Morning News, Architect, Rochdale Observer, Middlesex Courier, Birmingham Post, Leeds Mercury, Keene's Bath Journal, Leicester Post, Hereford Times, South Eastern Gazette, Windsor Chronicle, Yorkshire Post, East Anglian Times, Glasgow Evening News, Midland Counties Express, Sheffield Independent, Bristol Mercury, Chatham News, Bexhill-on-Sea Observer, Bury Guardian, Scotsman, Local Government Chronicle, Reading Mercury, City Press, Mining Journal, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Surrey Advertiser, Local Government Journal, Australian Medical Gazette, Sheffield Daily Telegraph, Western Mail, Sevenoaks Chronicle, West Middlesex Herald, Burton Chronicle, Aberdare Times, Jersey Weekly Press, &c., &c.*

The Lumleian Lectures

ON

SOME PROBLEMS IN CONNEXION WITH APHASIA AND OTHER SPEECH DEFECTS.

Delivered before the Royal College of Physicians of London, on April 1st, 6th, and 8th, 1897,

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,

CENSOR OF THE COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE II.[1]

Delivered on April 6th, 1897.

MR. PRESIDENT AND GENTLEMEN,—After the full discussion of physiological first principles in the last lecture, I now propose to limit myself to a consideration of certain parts only of the very extensive subject of speech defects, and I have selected those parts which are of most general interest and that have hitherto given rise to most discussion. I shall not deal at all with defects dependent upon lesions beneath the cortex—that is, neither with anarthria nor with aphemia; nor shall I consider, except incidentally, the effects of lesions of the commissures between the different word-centres. I shall confine my attention to the effects of lesions of the four word-centres themselves, both separately and in combination. And when I say lesions I mean for the most part gross lesions, for time would not permit of my dealing with the many varieties of aphasia due to transitory lesions or functional disabilities in Broca's region. And even when thus narrowing the subjects to be dealt with in this and the next lecture, I find myself over-burdened with matter—partly because of discordant views that must be discussed, and partly because in the present state of knowledge and opinion concerning these speech defects it would be impossible for me to attempt to substantiate my own opinions without quoting a number of cases the full details of which the time at my disposal will not permit me to read.

STRUCTURAL DEFECTS IN THE GLOSSO-KINÆSTHETIC AND CHEIRO-KINÆSTHETIC CENTRES.

These kinæsthetic centres are, as I have already observed, concerned more with the expression of thought than with the thinking process. Their activity is in the main roused as thought is about to translate itself into action. These centres form the last outposts on the side of ingoing currents, and constitute at the same time the starting points for outgoing currents. They are situated at what psychologists have spoken of as "the head of the stream." Although with lesions limited to these regions the power of thinking may not be very greatly interfered with, still it is nearly always interfered with to some extent, so that patients having such lesions do not usually exhibit anything like the same amount of mental clearness as that shown by patients suffering from aphemia. It is true that the latter very frequently preserve their power of communicating their thoughts by writing, whilst aphasic patients do so only rarely. Any mental disability in the latter would therefore tend to appear greater than it really is. But this only very partially explains the apparent difference in mental power that is commonly met with. The fact that speech and writing are so frequently involved together in typical cases of aphasia is due partly to the proximity of the glosso- and the cheiro-kinæsthetic centres, and, as we shall subsequently see, perhaps not less to the proximity of the two sets of commissural fibres connecting these centres with the auditory and the visual word-centres respectively. Damage to these commissures may, in fact, be a cause of typical cases of aphasia and of agraphia, as I shall subsequently endeavour to show.

These modes of accounting for the co-existence of agraphia with aphasia undoubtedly hold good for certain cases, and especially for those in which, while there is no paralysis of the right hand and arm, the agraphia is complete—copying (except laboriously and slowly) being no more possible than writing spontaneously or from dictation. The destruction either of the cheiro-kinæsthetic centre or of the commissure connecting it with the visual word-centre ought to produce such decided results as this. On the other hand, if no other disturbing cause were in operation, there is no reason why such a patient should not be able to write well with separate wooden letters (*écriture typographique*) either spontaneously or from dictation. And in cases where such a patient is paralysed in the right hand there would be no reason why he should not, with practice, become able to write in all modes with his left hand.

Whether the combination of aphasia and agraphia is mostly due as I think, to this simultaneous implication or functional derangement of the cheiro-kinæsthetic centre and the commissure uniting it with the visual word-centre or to some other cause must for the present be regarded as a moot point. Formerly a different view was taken. Thus some of the earlier observers of aphasic cases, such as Trousseau, Hughlings Jackson, and Gairdner, seemed to consider that the inability to write was as much a result of a lesion in Broca's centre as inability to speak, and contended, indeed, that there was almost always a parity between these defects. Trousseau,[2] for instance, says: "The inability to write is proportionate to the inability to speak"; and again: "Aphasics write as badly as they speak, and those who do not speak at all are absolutely incapable of writing." Gairdner expresses himself in almost similar terms. Hughlings Jackson is even more decided in his opinion. Thus he says[3]: "If a patient does not talk because his brain is diseased, he cannot write (express himself in writing). ..... I submit that the facts that the patients do not talk, and do write and do swallow, are enough to show that there is no disease at all."

One of the first to dwell upon the marked inequality that may be met with between these two disabilities was W. Ogle,[4] to whom we owe the introduction of the term "agraphia." More than ten years previously, however, Marcé[5] had insisted upon the independence of these two defects. Thus, speaking of inability to write, he said: "It is independent of the faculty of expression [by speech], since twice the patients could write freely when they were quite unable to speak. It is independent of the motility of the hand, since even when the hand has preserved all its power writing has been found to be impossible."

The dependence of ability to write upon the integrity of a cortical centre altogether distinct from that by which articulate speech is effected is, I think, practically certain, but this is but another aspect of the question previously put, and will have to be considered more fully a little later. For the present it is assumed that there are two such separate but contiguous centres; and if this be true, that they are frequently affected simultaneously (either structurally or functionally) in cases of aphasia may be fully recognised. Still in some cases either the glosso-kinæsthetic or the cheiro-kinæsthetic centre seems to be in the main involved, so that in one case speech may be principally interfered with, while in another it is more especially writing that is made difficult or impossible. This latter kind of defect is much less frequent, and usually less noticeable, than the former, because the patient is also often more or less paralysed in the right hand and arm. In such cases attempts at writing would only be possible, if at all, where the left hand and the right side of the brain have been more or less educated, and frequently no serious attempts have been made in this direction.

Though aphasic patients are unable to give voluntary and preconsidered expression to their thoughts; words, or even short phrases and oaths, may occasionally be uttered under the influence of strong emotion. We often find these patients able to make use of short familiar words like "yes" or "no" in response to questions addressed to them, though they may be often inappropriately employed. The articulation of such words, or "recurring utterances" as they are now commonly termed, is generally supposed to be brought about through the intervention of the comparatively uneducated right third frontal convolution, and this subject will be referred to more fully later. As Hughlings Jackson originally pointed out, such a patient is quite unable to repeat one of these words which he is continually bringing out, or, indeed, any other simple vowel sound, when he is asked to do so. He cannot utter it, that is, in a purely voluntary manner, in response to a request or command. Another interesting

peculiarity is also often seen when resident foreigners become aphasic. During recovery it is found that they are at first only able to express themselves in that language in which they are most thoroughly versed—namely, in their own native tongue. I have seen this in several patients. Two were Germans who had been long resident in this country; yet after an attack of right hemiplegia and aphasia each of them was for a long time unable to utter a word of English. When they began to speak they used German words only; and after they had further recovered, if occasionally in want of a word while speaking English, it was always a German equivalent that first presented itself.

There are many instances on record in which, though the aphasic condition itself has been complete and associated with more or less agraphia, the mental powers of the patients have been fairly well preserved. Many of such individuals have been able to read intelligently to themselves, and play games, like draughts or cribbage, perhaps better than their neighbours.

The powers of articulation and of speech remaining to aphasic patients are very various, but may generally be ranged under one or other of the following heads: (*a*) Cannot utter a sound, or only mutters inarticulately; (*b*) constantly repeats some meaningless sound or sounds such as "tan-tan" or "cousisi"; (*c*) uses some one or two single words such as "yes" and "no,"; and also mere sounds such as "ba-ba" or "poi-boi-ba"; (*d*) uses some short phrase habitually, such as "list complete," or "I want protection"; and (*e*) uses three or four words or expressions, though in themselves meaningless or irrelevant, in a constant and definite manner, as in Broca's case (Lelong), in which the words "oui," "non," "trois," and "toujours" were so employed.

An examination of the recorded cases in which aphasia has been produced by lesions more or less completely localised to Broca's region, or to it and the foot of the second frontal convolution (the supposed seat of the centre for writing), by no means suffices, as some suppose, to establish the view that agraphia is to be regarded as one of the effects of a lesion in the foot of the left third frontal gyrus. It will rather be seen, on the whole, to lend considerable support to the opposite notion that co-existing agraphia in such cases is to be regarded as a result of a coincident damage to, or functional perturbation in, the foot of the contiguous second frontal convolution. The evidence afforded by such cases, however, is much less conclusive than it should be, owing to the fact that in so few of them have careful observations been made as to the ability of the patient to write some days after the occurrence of the lesion, when the mere perturbation of brain functions that it may have caused has had time to subside.

Of the first two cases of aphasia that were recorded by Broca,[6] in one the lesion was old and widespread, though the left third frontal convolution was one of the parts that were destroyed; in the other the lesion was limited to the posterior parts of the left third and second frontal convolutions, and there was as a consequence loss of speech and writing, without any paralysis of limbs. This was, therefore, altogether the most memorable case, since by means of it more especially the first attempt was made to limit the situation of the region in the left frontal lobe damage to which gave rise to aphasia. The following is an abstract of this classical case:—

CASE 1.—Lelong, aged eighty-four years, was admitted into the surgical ward of the Bicêtre, Oct. 27, 1861, under the care of Broca. In the month of April, 1830, he had had a slight apoplectic attack, from which in a few days he was convalescent, no paralysis of limbs having been observed, though his speech was lost except for four or five words. His intelligence seemed unimpaired. He understood all that was said to him; and apart from his very scanty vocabulary he made use of expressive gestures. He remained in much the same condition for eighteen months, that is up to the time of his coming under Broca's care. To his questions he only replied by signs, accompanied by one or two syllables pronounced hastily and with visible effort. Broca says:—"These syllables had a meaning. They were French words, viz., *oui*, *non*, *lois* (for *trois*), and *toujours*. He had a fifth word, which he pronounced when one asked his name. He then replied, 'Lelo' for Lelong, his real name. . . . The first three words of his vocabulary corresponded each to a definite idea. In affirming or approving he said 'oui.' In expressing the opposite idea he said 'non.' The word 'tois' expressed all numbers, all numerical ideas. And lastly, whenever these three words were not applicable Lelong helped himself with the word 'toujours,' which in consequence had no definite meaning. I asked him if he knew how to write 'oui'; if he could do it. 'Non.' 'Try.' He tried, but he could not succeed in directing the pen." Broca gives details of his conversations with Lelong in illustration of these points. His sight and hearing were good. The tongue was protruded straight and was moveable in all directions. There was no paralysis of the limbs. This patient died twelve days after his admission, and at the necropsy the remains of an old hæmorrhage was found in the form of a small cavity filled with serum, and having its walls infiltrated with altered blood pigment, occupying the posterior third of the second and third frontal convolutions. This was evidently the lesion which occurred when he suddenly lost his speech about twelve months previously, as other parts of the brain showed no focal lesion of any kind.

[6] Bulletin de la Société Anatomique, 1861.

Tamburini and Marchi[7] have also recorded a case of destruction of the second and third left frontal convolutions which was associated during life with aphasia and agraphia.

Another case has been recorded by Simon[8] in which there was a traumatism affecting these same convolutions.

CASE 2.—A perfectly healthy man fell from his horse. He got up at once, took hold of the bridle, and was about to vault into the saddle, when a physician, who by chance accompanied him, approached and examined him. He was unable to speak, but made himself understood by signs. No paralysis whatever was present. On the head there was a small wound with depression of the bone. Later, when death ensued from meningitis purulenta and inflammatory softening of the brain, a bit of bone that had been broken off was found in the left third frontal convolution which, together with the second and the island, was softened. In the skull there was only a perfectly round hole, no crack or fracture in any part.

Nothing is said here as to the presence of agraphia, but it would probably have manifested itself as soon as the inflammatory softening caused by the original traumatism had extended so as to involve the posterior part of the second frontal convolution. Probably the condition of the patient, however, was too serious to permit of this being tested.

A case has been recorded by Rosenstein[9] in which it is said that a hæmorrhagic softening involving the third frontal convolution only gave rise to both aphasia and agraphia.

CASE 3.—A woman, aged twenty-two years, was admitted into hospital suffering from a fever of intermittent type, and from nephritis. She was ill for several months, and whilst recovering from this affection she was suddenly seized with severe cerebral symptoms. The countenance was pale, the expression staring, the pupils dilated. She understood what was said to her, and put out the tongue when asked. She took a drinking-glass when it was offered to her. She tried to answer, but in reply to questions could only say "Ja, Ja." She nodded approvingly when one guessed what her wishes were. She had formerly been able to write well, but now when requested to do so she only made all sorts of scrawls, but no letters. She lived sixteen days longer without the aphasia disappearing, and then died from a thoracic complication. At the necropsy a clot the size of a hazel-nut was found in the third frontal convolution, surrounded by a limited area of secondary softening. The precise site of the clot in the third frontal convolution is not stated.

In regard to this case it may be fairly said that the sudden irruption of a clot of blood of the size of a hazel-nut into the third frontal convolution may well have inhibited for a time the functions of the immediately adjacent portion of the second frontal convolution, and it is also by no means clear that the secondary softening may not have slightly extended into this part.[10] It will be of interest here, also, to quote a case of combined aphasia and agraphia in association with right hemiplegia, and therefore presumably the result of a much larger lesion. It is one of the cases recorded by Trousseau,[11] but in which there was no necropsy. The patient was, as is very often the case in true agraphia, able to write his own name, though nothing else. Trousseau says:—

CASE 4.—"In August, 1863, a lady came to consult me with her son, aged twenty-five years. Four years previously this young man had for several days complained of headache, when he suddenly called out to his mother one morning, 'Oh! I feel something extraordinary inside me.' These were the last words he spoke. His right arm and leg became numb, and after a few hours the hemiplegia was complete. After a short period he regained some power of moving first his leg and then his arm; but when he came to me he still walked with difficulty, and could only use his hand for very rough purposes. The aphasia, however, which had from the first day been complete, had not diminished. He could articulate two words only—'No' and 'Mamma.' 'What's your name?' 'Mamma.' 'What's your age?' 'Mamma, No.' He yet knew that he did not answer as he ought. He had taught himself to write with the left hand, but had not got beyond signing his own name, Henri Guénier. He wrote it very legibly on a piece of paper which I gave him. 'Since you write your name,' I then told him, 'say Guénier.' He made an effort, and said 'Mamma.' 'Say Henri.' He replied, 'No, Mamma.' 'Well, write Mamma.' He wrote 'Guénier.' 'Write No.' He wrote again 'Guénier.' However much I pressed him I could obtain nothing more. His mother informed me that he could play a pretty good game of cards or dominoes."

Here we do not know the extent of the lesion. In such a case, however, it would have been immaterial whether the second frontal was involved in the lesion or not, because, as I shall subsequently show, destruction of this centre together with Broca's centre would not prevent a patient learning to write with his left hand, provided the left auditory and visual word-centres were not damaged at the same time. No sufficient details are given by Trousseau to enable us to decide whether the visual word-centre was or was not affected. It certainly may have been, judging from the fact that this young man had been unable to do more than learn to write his own name during the four years that had elapsed since the commencement of his illness—this being generally the extent of the achievement in this direction of patients who are agraphic by reason of a defect in the visual word-centre. Although this case, therefore, may have influenced the opinion of Trousseau, the modern development of knowledge enables us to say that it furnishes no evidence in elucidation of the question whether or not agraphia as well as aphasia is a necessary result of a lesion limited to the left third frontal convolution. I say this with all the more confidence because W. Ogle has recorded a case in which there was right hemiplegia and aphasia, though the patient could write with the left hand, and at his death the second left frontal convolution was found to be intact.[12] The essential details in this case are these :—

CASE 5.—A man, who had suffered from rheumatism and was the subject of aortic and mitral disease, had three days before admission to hospital fallen down, without loss of consciousness, and had found himself hemiplegic and aphasic. On examination, his speech was found to be limited to the two words "yes" and "no." At first he had difficulty in deglutition and in putting out his tongue, but these symptoms passed away in a few days. He understood all that was said to him, and expressed himself well by pantomime. In regard to his writing W. Ogle gives us the following information: "He could write with his left hand with sufficient distinctness words which he could not pronounce when asked to do so. In his writing there was often a tendency to reduplication of letters. For instance, he wrote 'Testatament' for Testament. But I cannot say whether this was more than the result of defective education." The necropsy showed the brain to be healthy, except at two limited spots, of which the chief was the posterior part of the third frontal convolution on the left side. Here was a softened and almost diffluent patch, about three-quarters of an inch in breadth, reaching from the highest part of the third convolution backwards and downwards to the fissure of Sylvius. The softened part was not actually the most posterior part of the convolution, for there was a narrow unsoftened strip between it and the transverse (ascending) frontal convolution. On cutting into the brain a second small patch of softening was seen in the centre of the left hemisphere, external to and rather above the corpus striatum, and extending towards the posterior extremity of the fissure of Sylvius.

Here, then, where we have the third left frontal affected whilst the second frontal convolution was proved to be healthy, there was aphasia, but no agraphia; and we may, perhaps, assume that a similar exemption from disease of the second frontal convolution existed in a case of my own in which there was a similar combination of symptoms.

CASE 6.—An active and intelligent man, a builder by trade, had an apoplectic attack associated with convulsions, which left him paralysed on the right side and quite speechless at first. His mind was also much confused for a time, but after two or three weeks he became able to understand what was said to him. The only articulate sounds he was able to utter for the first nine or ten months were "bi-bi-bi," "poy-boy-ba," and "no." After fifteen months he became able to say both "yes" and "no" appropriately; though whilst he continued under my care I never heard him utter any other articulate sounds than those above cited, and according to the statements of his wife this was the extent of his vocabulary. He had regained almost the complete use of his right leg, though the hand and arm still continued very powerless. He had practised writing with his left hand, and wrote fairly well with it. He was asked to write a letter to me, and the next time I saw him he gave me a note of which the following is a literal copy:—

"Jany. 5, 1869.

"Sir,—I am extremely obliged to you for the trouble you have taken about my affairs. You did not say thether *(sic)* you hav recovered from the severe cold and cough that you told me you were suffering from. I sincerely hope that you have quite recovered your health and strength.

"I am,

"_____."

This note was written, his wife informed me, in less than half an hour, and without any assistance. Yet since his attack this same patient had only been able to utter the two or three words and sounds above mentioned. He seemed to understand everything that was said to him, and appeared also to understand the newspaper equally well when he read it, which he did habitually. When told to count twenty by tapping on the table with the forefinger of the left hand, he did it rapidly and always correctly. . . He could add quite correctly columns containing five figures when the numbers were low, but often got puzzled and made mistakes when the numbers were higher. According to his wife's statement he had been much more irritable than he was before his illness. He had several epileptiform attacks after the one with which his illness commenced, and on each occasion the convulsions were almost limited to the right side of the body.

In each of these cases, even where there has been no agraphia, there has been a more or less distinct lowering of mental power, as compared with that which occurs in the class of cases due to subcortical lesions which I include under the term "complete aphemia." For this there are two causes. First, there is the fact that in these cases of aphasia the brain may have been more considerably and widely damaged by the various structural lesions that have occurred than has been the case in the aphemic group of cases. Secondly, there is the fact that in the cases of aphasia one kind of word-memory is blotted out, whilst in aphemia none of the forms of word-memory are interfered with. Although the kinæsthetic memory of words is, as I have previously said, much less important for the carrying on of thought processes than the revivals which occur in the auditory and in the visual word-centres, still the destruction of the glosso-kinæsthetic centre may interfere with the functional activity of the other two centres. And this interference with the customary completeness of the processes of association concerned with thought and speech might be expected to lead to more or less of mental deterioration.

The degree to which this interference with thought occurs may, however, in an uncomplicated case of disease limited to Broca's region be extremely slight—almost inappreciable in fact—and moreover associated with no impairment in the power of writing. A very remarkable case of this type has been recorded by Guido Banti[13] which will well repay the most careful attention, because it speaks most authoritatively against the views of Trousseau and the other writers already referred to who have taught that agraphia, as much as aphasia, is a result to be expected from an isolated destruction of Broca's region.

CASE 7.—A right-handed man, aged thirty-six years, who was able to read and write correctly, had a sudden apoplectic attack in 1877. Recovering consciousness in a few minutes he was found to be suffering from right hemiplegia and loss of speech. The paralysis of the limbs disappeared almost completely during the following night, though the inability to speak persisted. The next day he was admitted into hospital, and on most careful examination his condition was found by Guido Banti to be as follows:—"The motility of the limbs on the right side had returned to their normal condition. There was no trace of paralysis of the face or of the tongue. The patient made ineffectual attempts to speak; *he could not articulate a single word*, not even isolated syllables. He was much affected by this mutism, and sought to make himself understood by gestures. I asked him if he knew how to write, and after he had made a gesture in the affirmative I gave him what was necessary and told him to write his name, which he did immediately. I put various other questions to him, to which he replied similarly by writing. I told him to give me a description of his illness, and *he wrote without hesitation* the details above reported. I showed him various objects, pieces of money, &c., telling him to write their names, and he did so without making any mistakes. Then instead of giving him these directions by word of mouth, I wrote them for him in order to thoroughly convince myself that he was able to understand writing. He replied to these questions with perfect correctness. He always wrote very rapidly and did not seem to hesitate to choose his words. He made no mistakes in syntax or orthography. He could understand equally well ordinary writing and print, and when one spoke to him he grasped at once the meaning of the questions, and never wished to have them repeated. I next wrote some most simple words, such as 'pain,' 'vin,' &c., and urged him ineffectually to read them aloud. I then pronounced myself some of the words, directing him to repeat them. He appeared to watch with great attention the movements of my lips whilst I spoke; he made some ineffectual efforts to obey, but he never succeeded in pronouncing a single word." This patient died in February, 1882, from an aneurysm of the aorta; and a patch of yellow softening was found situated in the posterior third of the third left frontal convolution, and extending for some millimetres only into the white substance.

Here, then, we have a patient with a lesion destroying, but limited to, Broca's region, in whom there was loss of speech but no trace of agraphia, the patient being able to write well with his right hand. It is also of importance to note that there was here no more mental impairment than is found to exist where speechlessness is due to a sub-cortical or a bulbar lesion—that is, in a case of aphemia or of anarthria. But for the result of the necropsy I should have regarded this case as one of complete aphemia. It shows, therefore, that there may be no clinical differences present to enable us to make this differential diagnosis, even though in the one case we have destruction of Broca's region, and consequently no kinæsthetic revivals of words possible, while in the other this kind of word memory is in no way interfered with, and there is also less chance that the lesion would lead to any interference with the functions of the auditory and the visual word-centres. For another very interesting case of aphasia in some respects similar to the last I am indebted to the kindness of Dr. Dickinson.

CASE 8.—A sailor, aged forty-nine years, was admitted to St. George's Hospital under Dr. Dickinson's care, having had a fit in a neighbouring public-house. He had landed a few days before, and had been robbed in some place of resort for sailors, and had been much disturbed in mind in consequence. One and a half hours after admission he had recovered consciousness and intelligence, but not his speech. He could not say anything intelligibly except the word "no," but the remarkable fact about his case was that he could express himself perfectly in writing, which he did with his left hand. He was hemiplegic on the right side, the right arm being completely powerless, the right leg partially so; there was also slight loss of sensibility over the whole of the right side of the body. For three weeks his speech was limited to the use of the word "no," a sound like "yong" which stood for "wrong," and the frequent repetition of the syllables "yah yah," which stood for everything. Told to repeat a sentence or phrase, "Great Britain and Ireland" or any other, he uttered the same "yah yah yah" for either. But he could express himself in writing as fluently and correctly as if his faculty of spoken language were uninjured. He wrote daily reports and an autobiography during the time that he was unable to speak. He understood perfectly all that was said to him. He retained his sense of music, and could whistle "God Save the Queen." On the twenty-fourth day after the seizure it was evident that his speech was improved; he could say "doctor" and "better." In the evening his full power of speech was rather suddenly restored. The limbs recovered more gradually, the leg sooner than the arm. He left the hospital six weeks after admission, able to walk, but not to lift his right arm. Dr. Dickinson adds:—"The perfect ease and fluency with which the man wrote with his left hand showed that he had been in the habit of doing so. He was in common phrase left-handed, though he said he was not to be called so, since he used both hands equally."

Though in many respects different from the case previously recorded, this resembles it in the fact that we have to do with what certainly seems to be a simple case of aphasia without appreciable mental degradation and with the power of writing unimpaired. The case is also interesting since it constitutes an exception to the very general rule that left-handedness suffices to transfer the leading speech activity to the right side of the brain, and because of the further exceptional circumstance that being left-handed the patient had not been taught to write with his right hand. Another case that was recorded many years ago by Wadham[14] is in some respects even more remarkable, and all the more convincing because it was followed by a necropsy. It will be observed also that before death the patient had regained his power of speaking. The essential details are as follows:—

CASE 9.—A youth, aged eighteen, left-handed and ambi-dextrous, became partly hemiplegic on the left side and completely speechless after long exposure to cold, and was admitted to St. George's Hospital under the care of Dr. Wadham. Twelve days later, on being given a slate and pencil, he wrote readily the word "orange," and when asked his name also wrote that correctly with his right hand, although his mother asserted that she had never previously seen him do so. He and four of his brothers were left-handed. About a week after this, being still absolutely speechless, when asked whether he tried to speak and was unable he wrote "Yes." Asked if when well he wrote with his right or with his left hand, he wrote "Both," and then added, "Fight with left." In six weeks' time the left hemiplegia had much diminished, but he had still never spoken a word and continued to write all his wishes on a slate. His manner gave the impression of his "being very intelligent and rather facetious." At the expiration of three months he left the hospital, and when seen at his own home two weeks later Dr. Wadham says: "I found that at his mother's dictation he repeated after her various words and sentences with the intonation employed by one who endeavoured to speak without moving his tongue." This power was gradually increased until at last he was able to talk with sufficient distinctness to be perfectly understood by those accustomed to him. He subsequently suffered from necrosis of the jaw, and three months after his discharge was re-admitted to the hospital. After an operation on the jaw he became able to move his tongue naturally. His articulation subsequently was indistinct, but he "had no difficulty in producing words, and always used the right ones." He died twelve months after the onset of his illness. At the necropsy a large area of softening was found in the right hemisphere, involving part of the white substance beneath the Rolandic area, and completely destroying the island of Reil. The left hemisphere was found to be perfectly healthy.

It may be thought by some that these two cases have little bearing upon the question we have been considering. But this would be an erroneous impression. Certain authorities maintain, as I have said, that destruction of the third frontal convolution alone in the leading hemisphere for speech gives rise to agraphia as well as aphasia. They believe, for reasons that will be more fully specified presently, that destruction of Broca's centre hinders the revival of words also in the other word-centres, and thus prevents writing by stopping the process at its source. But in the cases of Ogle, of Guido Banti, and of Wadham—and possibly in that of Dickinson—we see that the ability to think and write was not interfered with by such a lesion in the leading hemisphere for speech, and therefore that the activity of the corresponding auditory and visual word-centres was neither suppressed nor gravely interfered with.[15]

The case reported by Wadham is further of special importance because it has been contended by Déjerine and also by Mirallié,[16] upon the basis of four cases (without necropsies) of aphasia with left hemiplegia occurring in left-handed persons, in whom the power of writing was lost simultaneously, that this loss is the rule and only what might be expected. The cases I have cited show, however, that it is not the rule, and leave us free to suppose that those of Bernheim, Parisot, Magnan, and Déjerine (where the power of writing was lost) were not cases of simple aphasia due to lesions in Broca's region only. The lesions in them may also have involved the visual word-centre in one or other hemisphere, or the commissure between them, and in either of these eventualities we might find an explanation of the co-existing agraphia.

In all the cases of left-handed persons in which the right hemisphere takes the lead in speech, whilst the left hemisphere executes the writing movements, it must be supposed that the right auditory word-centre is the initial centre for the revival of words either for silent thought or for speech, and therefore also for spontaneous writing. Thus in such a person we must assume that the left visual word-centre becomes educated concurrently during the process of learning to write (through the commissural fibres in the corpus callosum), and that the writing process is executed by this left side of the brain in the ordinary way by the passage of stimuli from the visual word-centre on to the corresponding che'ro-kinæsthetic centre.[17]

There is, therefore, no reason whatever why some, and perhaps the majority of, left-handed persons when they become the subjects of left hemiplegia and aphasia should not, after the shock attendant upon the brain lesion has passed, either be able to write at once, as was the case with Dickinson's patient and with the ambi-dextrous patient of Wadham, or else speedily learn to do so. Where there is not this ability after a time, as in the case of Trousseau and one subsequently to be referred to which has been recorded by Déjerine, there would, as I have said, be fair ground for suspecting that the lesion was not confined to Broca's convolution, but was also associated with some damage to the visual word-centre either on the same or on the opposite side of the brain.

Returning from this partial digression concerning the mode in which writing is performed in some aphasic persons, it will be seen that the case of Guido Banti, as well as that of Dickinson and of Wadham, is absolutely opposed to the views of Stricker and Hughlings Jackson. They show that for mere thought, apart from its oral expression, the memorial recall of kinæsthetic impressions may be even less necessary than might have been supposed by those who do not share their views. These cases are equally opposed to the views of Déjerine, Wyllie, Mirallié, and others, who, without looking upon this form of word-memory as the most important of all, nevertheless think that glosso-kinæsthetic revivals are necessary for silent thought, and that without such a process as an initiative there is an inability to recollect words (amnesia verbalis), together with an inability to read and write.[18]

Déjerine seems to have been led to these views in the first place by adopting as does Wernicke, the opinion expressed by Trousseau, Jackson, and Gairdner, that a lesion limited to Broca's region carries with it agraphia as well as aphasia, and that the two defects are almost always proportional to one another. The frequent co-existence and parity of the two defects cannot be denied, but this, as we have seen, may be due to the common simultaneous damage to the glosso- and the cheiro-kinæsthetic centres, or to the commissures connecting these centres respectively with the auditory and the visual word-centres.

[14] St. George's Hospital Reports, vol. iv., 1868, p. 245.

[15] Dally (Ann. Med. Psychol., 1882, p. 252) mentions the case of another left-handed man who had an apoplectic attack resulting in left hemiplegia and aphasia, who was not agraphic, though he wrote in a paragraphic fashion. Two years afterwards he had almost recovered from his hemiplegia, and he could write, speak, and read, though he was unable to spell properly. M. Mesnet mentioned also that he had formerly presented to the society a patient suffering from left hemiplegia and aphasia with preservation of ability to write.

[16] Loc. cit., p. 85.

[17] The process of learning to write here would, in fact, be the converse of what occurs when an ordinary right-handed person suffering from right hemiplegia and aphasia learns to write with the left hand. The only other possibility would seem to be that the incitation for writing should pass direct from the visual word-centre in the leading speech hemisphere (though in a diagonal direction) to the centre for writing in the opposite hemisphere, which seems to me much less probable.

[18] Thus Wyllie, who follows Déjerine, goes so far as to say (loc. cit., p. 314): "There is reason to believe that in every case of severe motor aphasia that is due to destruction of the motor images amnesia verbalis is extremely well marked—even more so, perhaps, than it is in severe cases of auditory aphasia."

Hosted by Google

A careful examination of the cases capable of throwing light upon these two interpretations, to some of the best of which I have above referred, tells distinctly against the view, which has been adopted by Déjerine and others, that agraphia is to be regarded as one of the consequences of an isolated destruction of Broca's centre. The fact, however, of Déjerine adopting this view has led, I venture to think, to his attaching an altogether undue importance to destruction of Broca's region, since he not only believes that it interferes with silent thought by hindering the revival of auditory word images, but that it leads to some amount of alexia, and is likewise a cause of agraphia. It has also induced him to bring forth a variety of arguments tending, as he thinks, to disprove the existence of any cortical centre having the same relation to writing movements that Broca's centre has to speech movements. All these positions have, moreover, been recently maintained by his pupil Mirallié in a valuable and interesting work entitled "De l'Aphasie Sensorielle." It will be necessary, therefore, to look at these various opinions in succession, in order to see how far they are warranted by existing knowledge.

1. Does destruction of Broca's region alone entail amnesia verbalis?—To this question I am disposed to give a negative answer. I rely upon the reasons previously adduced to show that words are primarily revived in the auditory word-centre rather than in the glosso-kinæsthetic centre. I can also refer to the case of Guido Banti, as well as to those of Dickinson, Wadham, and others, seeing that the ability of these individuals to write clearly showed that they could recall words and were not suffering from amnesia verbalis. It is true that Lichtheim also agrees with Déjerine and Wyllie in regard to this question. Thus he says[19]: "I think that in most motor aphasics—in those, among others, of the true Broca's type—the patient has lost the auditory word-representations—that is to say, cannot awake them voluntarily by an action of their higher centres." The only safe criterion, he thinks, of the preservation of the auditory symbols in these cases would be obtained by the existence of an ability to write, or, in default of that, the ability to realise the correct number of syllables in any word that cannot be uttered, and to signify this number by giving so many hand-pressures. Both these powers are, he thinks, usually lost in patients suffering from motor aphasia. It has been shown, however, that this is not so in uncomplicated cases of destruction of Broca's region, since, as we have seen, the power of writing persists, and so doubtless would the other test of minor significance to which he refers. I am quite prepared to admit, however, that exceptions to this rule may be occasionally met with. The functional relations of the auditory word-centre with Broca's region on the one side and the visual word-centre on the other are so close that the destruction of either of these centres may be easily conceived to derange the functional activity of the others for a longer or a shorter time. The degree of this derangement may be considered to vary in different persons, perhaps in accordance with the relative potency, original or acquired, of the several centres. Thus in some persons an isolated destruction of Broca's region may disturb to a very slight extent the functional activity of the auditory and the visual word-centres, whilst in others it is quite possible that the severance of this centre from the other two may greatly alter their functional readiness, so that the spontaneous revival of the auditory and visual images of words may in such persons be more or less hindered, and as a consequence the power of thinking and of writing proportionately lowered.

2. Does destruction of Broca's region entail alexia?—I believe that, as a rule, in reading a proper comprehension of the meaning of the text requires a conjoint revival of the words in the visual and the auditory word-centres, but that for this mere comprehension it is not necessary for the stimulus to pass on also to the glosso-kinæsthetic centre, as it must do in reading aloud. It may, however, be freely admitted that if the way is open, and this latter centre is in a healthy condition, it does commonly receive in reading to one's self a slight stimulus from the auditory word-centre, a fact which is often enough shown by the occurrence of involuntary half-whispered mutterings when reading. It may also be admitted that the rousing of all three centres does give assistance in the comprehension of anything difficult, as is shown by the common practice of reading aloud any passage the meaning of which may be at all obscure. By this proceeding aid is obtained, however, not alone by the full rousing of the glosso-kinæsthetic centre, as there is also the full activity of the auditory word-centre following upon the spoken words. This kind of aid is, indeed, commonly needed, as Wernicke pointed out, by an uneducated person for the full comprehension of almost all that he reads. Therefore it may easily happen when such a person becomes aphasic from destruction of Broca's region that alexia may go with the aphasia.[20] Similar aid may be necessary in cases in which there is functional weakness of the visual word-centre. Thus there is now under my care in the National Hospital for the Paralysed and Epileptic a woman, apparently suffering from a tumour in the left hemisphere, who is hemiplegic on the right side and understands readily all that is said to her, but who does not seem to gather the meaning of the simplest written or printed request unless she reads it aloud, which she is able to do without hesitation. She is quite unable to write spontaneously or to copy with the left hand, but then she has made very few attempts in this direction since her right hand became paralysed.[21] It would seem, however, that in some persons the comprehension of writing or printing does not even require the associated activity of the auditory word-centre, so long as the visual word-centre is in a healthy condition and its other associational fibres are intact. This is proved by the fact that in a case recorded by Wernicke and Friedländer,[22] in which there was aphasia associated with word-deafness (due to a lesion in Broca's region and also in the upper temporal convolution), the patient was able to read well and even to write; there is also a valuable case of word-deafness (with lesions in both upper temporal convolutions) recorded by Mills, and to be quoted further on (Case 26), in which the patient was able to understand what she read; and a still more remarkable case recorded by Pick, with very similar lesions (Case 30), in which, although the patient was word-deaf, he could write and comprehend perfectly what he read.

Long before I was aware of the crucial evidence afforded by these cases and that of Guido Banti I did not believe that the comprehension of writing or of print was appreciably interfered with by an isolated destruction of Broca's region—that such a lesion, in fact, did not lead to alexia. For independently of the general views discountenancing such a notion there were Case 6 and two recorded cases by Broadbent, as well as others, pointing in the opposite direction. Some particulars concerning one of these cases recorded by Broadbent may well be reproduced here.[23]

CASE 10.—A man, aged twenty-nine years, was admitted to St. Mary's Hospital on April 3rd, 1870. He had had fits when a child, the last at the age of seven years; and rheumatic fever twelve months previously to his admission. He had not been well, and had left off work for two days. During these two days he talked incessantly all sorts of nonsense. In the night his brother awoke and found him in violent convulsions, mostly of the legs, not more on one side than on the other. The attack lasted two hours; when it was over right hemiplegia with loss of speech was established. On admission the paralysis was complete, the loss of speech absolute, and he could not protrude his tongue. He gradually gained some power in the leg so as to be able to walk about, but the arm remained motionless and flaccid. He could now also say "yes" and "no," but was not always right in his use of these words. On one occasion he twice said "Here" to his sister, when impatient that she had not complied with his wish for her to come to him. He could write his name, but nothing else; and wrote it when asked to write an answer to a simple question. Broadbent adds: "The case presented no unusual features, and is here recorded partly as an example of a rather unusual type of attack in embolism; partly for the purpose of noting that the patient while in the condition described read the newspapers much with apparent interest, and at my request he pointed out a Crystal Palace advertisement of fireworks and an account of pigeon shooting at Hurlingham, the latter very promptly and with a pleased expression, as if he had already read and enjoyed it."

Many of the cases in which there has been alexia co-existing with aphasia are I think clearly cases in which there have been rather wide lesions extending far beyond the third frontal convolution and involving also the visual word-centre. This is the interpretation that I attach to a celebrated case recorded by Trousseau, which evidently influenced his opinion very much. I allude to the wealthy patient whom he saw in consultation in the department of Landes.[24] On this point Trousseau says: "As he always answered 'Yes,'

I asked him whether he knew how that word was spelt, and on his nodding assent I took up a large quarto volume with the following title on its back, 'History of the Two Americas,' and requested him to point out the letters in those words which formed the word 'yes.' Although the letters were more than one-third of an inch in size, he could not succeed in doing as I wished. By telling him to seek for each letter in turn, and by calling out its name, he managed, after some hesitation, to point out the first two, and was very long in finding the third. I then asked him to point out the same letters again, without my calling them out first; but after looking at the book attentively for some time, he threw it away, with a look of annoyance which showed that he felt his inability to do as I wished him." Few, I think, would now suppose that we had to do here with a case in which there was no lesion about the posterior extremity of the Sylvian fissure as well as of the third frontal convolution.

Lichtheim is inclined to give much the same kind of interpretation to this class of cases. He points out that the examination of an old case is apt to be confusing in regard to its correct pathogenesis, owing to the fact that some of the defects originally existing have cleared up and disappeared. In this relation he calls attention [25] to the "usually rapid disappearance of word-deafness, and the greater persistence of the troubles connected with written language." He adds: "This fact appears to me to throw light upon a not unfrequent type which does not readily fall in with our classification; I mean that of motor aphasia in which alexia co-exists."

It is, of course, possible that this explanation by Lichtheim may hold good for certain cases, but that it is not necessary to have recourse to it in order to explain those cases of apparently simple aphasia with which alexia co-exists I have become convinced by two cases that have recently come under my observation. What we have to ask ourselves when in the presence of such cases is whether there is any evidence to show that the case is not one of simple aphasia, and whether a lesion exists also in the region of the posterior extremity of the Sylvian fissure. We may inquire, therefore, for the previous existence of word-deafness as Lichtheim suggests, and also examine the patient carefully for the present existence of some amount of hemianæsthesia. The finding of this latter would show two things: first, that the lesion was not limited to the third frontal convolution; and, secondly, that either it or a second lesion also existed not far away from the visual word-centre, which consequently may have been also involved. Since I resolved to apply this test two cases of aphasia combined with alexia have come under my care, and in both of them there was the co-existence of a more or less complete hemianæsthesia, as may be seen from the abstracts of these cases which I now give.

CASE 11.—A woman aged thirty-two years, was admitted into the National Hospital for the Paralysed and Epileptic under my care on May 19th, 1896. She had been married fifteen years, and had eight children. She had a loud, mitral regurgitant bruit; the pulse was small, and irregular in force and frequency. She had been in good health till Oct. 25th, 1895, when she had a fit with loss of consciousness lasting three hours. For two or three days afterwards she seemed quite dazed and did not know anyone. The fit was followed by loss of power in the right arm and leg and loss of sight in the left eye. She has regained some power in the right arm and leg, but is still blind in the left eye. Ophthalmoscopic examination shows simple white atrophy of the left optic disc with evidences of past embolism of some branches of the central artery of the retina. She is naturally right-handed. There is distinct, though slight, right hemiplegia, including the face, arm, and leg. She can walk with dragging of the right foot and perform all movements with the right leg and arm, though much less forcibly than with the left limbs. The tongue is protruded straightly. There is incomplete right hemianæsthesia; sensation is dulled to touch and pain to the mid-line of the face, head, and trunk (back and front), also over the arm, hand, and upper two-thirds of the thigh. She is almost completely speechless. She can answer "Yes," "No," and say "Yes, I know" in answer to questions. Once she said "Good night." Her articulation of these few words is good. She cannot speak voluntarily, and cannot repeat the simplest word when bidden. The patient understands more or less complex matters spoken to her, and performs some spoken commands, but is slow at it, and often makes mistakes. When told to show her tongue she generally shows her teeth. There is almost complete alexia. She cannot recognise words or letters as a rule, except short names of external objects, such as "pen," "lamp," "cat," "dog." She will, when shown the name, point to such objects in the ward or in pictures. She does not recognise the word "man," and she cannot understand simple written commands. When shown four or five capital letters she can very rarely point correctly to one that may be named. She does, however, recognise and point out numerals; she can add two numbers together, but cannot subtract or multiply. She can also pick out objects named; she cannot name them, but shows by her expression that she recognises their names when she hears them. She cannot write letters with either hand spontaneously or from dictation, but she can copy single letters printed or written—the former better than the latter. She cannot do transfer copying.

[25] Loc. cit., p. 467.

This case, though interesting, is perfectly simple and needs no comment. The next, though equally cogent, is a little more complex.

CASE 12.—A young woman, aged seventeen years, was admitted into University College Hospital under my care on June 20th, 1896. She had had rheumatic fever when a child, since which she had been always ailing, principally by reason of a heart affection. She had a loud presystolic bruit and some hypertrophy of the left ventricle. On June 8th, 1896, on awaking she found herself paralysed on the right side of the body. During the following day, without the occurrence of any fit, she lost her speech. During the first week of her illness she was very dull mentally, and there was incontinence of urine and of fæces. She also suffered from pains in the left side of the head. When admitted, on June 20th, the paralysis of the right arm and leg was complete, together with slight paralysis of the lower half of the face. There was well-marked right hemianæsthesia, but no hemianopia. There was ankle clonus, with increased knee, wrist, and elbow jerks on the right side. The limbs were flaccid. She was almost speechless. She understood all that was said to her, looked intelligent, and often attempted to speak, but then and since her illness the only words she had uttered had been "yes," "no," and "oh, dear!" She often said "Yes" inappropriately when asked a question, and then immediately shook her head in correction. She could not repeat a single word when bidden. She recognised objects such as pencils, paper, and pens, but could not name them. There was complete alexia; she did not understand written or printed words or short sentences; nor could she point correctly to individual letters. On June 22nd she could repeat short words uttered before her in a slow, hesitating manner, and with indistinct utterance. On June 27th she was much better; she could count up to ten, and say the days of the week when started; she could also name most common objects which she was shown. She could also read aloud short words in print or writing, and understand their meaning. On July 2nd she talked a little in short sentences, though her pronunciation of words was still indistinct, and she had difficulty in recalling the words she wanted. On July 8th she was still improving. She could then move her right leg a little. She talked slowly and indistinctly, but still had difficulty in recalling words, though she did not utter wrong words. She read aloud a few lines of short words from a book slowly, passing over some and miscalling other words. She seemed to understand what she read. Some right hemianæsthesia still existed.

When first admitted this patient seemed to present a typical case of aphasia, but for the existence of the alexia. The fact of the presence of hemianæsthesia showed, however, that the lesion extended back to the posterior third of the hinder segment of the internal capsule, or else that another lesion existed there—that is, in a region very close to the visual word-centre. This, of course, carried with it the possibility that the visual word-centre itself might have been temporarily disabled. The subsequent progress of the case—the speedy clearing up of the aphasia, owing probably to a restoration of the circulation through the first cortical branch of the left-middle cerebral, which may have been temporarily blocked, and the revelation then of some amount of amnesia verbalis—made it all the more likely that the alexia was to be explained by some temporary disablement of the visual centre. That the auditory centre was only slightly (though more durably) affected was shown by the fact that there was never word-deafness and by the patient's subsequent ability to read even better than she could speak spontaneously.

The probability is, therefore, that in the cases of associated aphasia and alexia recorded by Trousseau and others the latter defect is not to be regarded as a consequence of the lesion in Broca's region, but rather as a result of some co-existing damage to the visual word-centre.

3. Does destruction of Broca's region entail agraphia?—The writers whom I have previously named say yes, that agraphia as well as aphasia is entailed by an uncomplicated lesion in the posterior part of the third frontal convolution. But with this doctrine, as already stated, I cannot agree. In writing spontaneously or from dictation there is, I believe, needed for most people a primary revival in the auditory word-centre and secondarily in the visual word-centre, whence combined stimuli pass to the cheiro-kinæsthetic centre, and thence well over in coördinated form to the motor centres in the cord by which the actual writing movements are effected. The evidence that I have already recorded is quite in harmony with this view, whilst it is entirely opposed to the doctrines on this subject formerly enunciated by Trousseau, Hughlings Jackson, and Gairdner, and which have been recently advocated by Déjerine, Wyllie, Mirallié, and others.

4. Is it right to deny the existence of a special centre for the registration and regulation of writing movements?—We are now brought to the consideration of Déjerine's objection to the very existence of a special centre for writing movements—a "cheiro-kinæsthetic centre" as I name it. His reasoning here seems to me rather surprising, and is of such a nature as to make it necessary to premise that the case of writing is almost exactly comparable with that of speaking—and, indeed, of all other habitual voluntary movements, whether

Hosted by Google

complicated or simple. Each set of movements must be associated with a set of ingoing impressions (kinæsthetic), which are registered in different portions of the Rolandic area of the cortex. This must be as inevitably true for writing movements as for speech movements; and, just as re-excitation of Broca's region under stimulation from the auditory word-centre is necessary for speech, so a re-excitation of the centre in which the impressions generated by writing movements are registered is, under stimulation from the visual word-centre, needful for the production of writing movements.

Yet both Wernicke and Déjerine say that the intervention of a special centre for writing movements is not necessary, on the ground that writing consists in a simple copying of the visual images stored up in the visual word-centres. This, however, is extremely vague. It must be asked, How is the copying achieved? That is, By what cerebral mechanism is it brought about? I maintain that the visual word-centre cannot act directly upon the motor centres in the cord, and that the conjoint activity (for coördinating purposes) of a kinæsthetic centre is quite as essential in the case of writing movements as is the activity of Broca's region for the production of speech movements. By parity of reasoning Wernicke and Déjerine might just as well say that Broca's centre is not needed, on the ground that speech consists in a simple copying of the auditory images stored up in the auditory word-centre, and hold that the auditory word-centre can act directly upon the motor centres in the bulb for the production of speech. But I contend that in each case another regulating centre must intervene, and that such a centre is just as essential for the translation of visual images into writing movements as it is for the translation of auditory images into speech movements.

Again, How can it possibly be alleged as a valid argument against the existence of a cheiro-kinæsthetic centre in a man accustomed to write with his hand that the same man is able to write on sand rudely with his foot, or that he can after a fashion write with his elbow, or with a pencil placed between his teeth? Clearly in these other crude modes of writing he would simply be dependent upon the activity of other parts of the general kinæsthetic centre. Such objections—for they are scarcely worthy of the name of arguments—are therefore altogether futile. The question that has to be considered is whether a man who has learned to write with his right hand, and who habitually writes in this fashion, calls into play a cortical centre the activity of which in the production of those movements is comparable with the activity of Broca's centre in the production of speech movements. To this question there can be but one answer. And the fact that in those cases of word-blindness in which the patient is able to write spontaneously he can subsequently succeed in reading what he has written, by tracing the outlines of the letters with his finger must also be taken as direct evidence of the existence of a cheiro-kinæsthetic centre, as I pointed out many years ago.[26] The impressions produced by the writing movements thus occasioned pass from their centre of registration back to the visual and auditory word-centres, and thus enable the writing to be read. Of course, a patient would not be able to read in this way if his visual and auditory word-centres were destroyed; therefore the objection of Déjerine and Mirallié to this evidence falls to the ground.[27]

Another argument adduced by Déjerine against the existence of a special centre for writing has been based upon an interesting case which he cites very briefly[28] of a patient, left-handed for all acts save those of writing, who became hemiplegic on the left side and aphasic, and at the same time lost the power of writing with his right hand. The patient continued in this condition for four years, and judging from the symptoms (there being no necropsy) Déjerine regarded it as a simple case of "motor aphasia." He thinks that the foot of the right third frontal was destroyed, and that this patient was as incapable of writing as of speaking because he had no longer a "notion of the word," owing to his supposed inability to revive verbal images. The fallacy of this inference has already been shown in part by the cases of Dickinson, Wadham, and others previously recorded; and in part by the evidence I have brought forward as to the non-occurrence of alexia as a consequence of destruction of Broca's region. This latter evidence goes to show that in many cases of what at first sight appear to be cases of simple "motor aphasia" with alexia there is reason for believing that a lesion exists in the hinder part of the hemisphere which may have damaged the visual word-centre. A lesion in this situation may therefore have existed in the case under the care of Déjerine, and thus have accounted for his patient's inability to write as he had been accustomed to do with his right hand. For if his previous power of thinking in words had depended upon the activity of the word-centres in the right hemisphere, then spontaneous writing would have required the activity of the auditory and visual word-centres of this side as a first stage in the process, and secondly that they should be in relation (through the corpus callosum) with the similar centres in the left hemisphere, so that the proper stimuli might be passed on to the left cheiro-kinæsthetic centre for the bringing about of writing movements by the right hand. A damage to the visual word-centre of the right side would therefore have caused this patient to lose his previous power of writing with the right hand. The case under the care of Déjerine therefore admits of an explanation quite different from what he has given to it, and which is also much more in accordance with existing knowledge. Clearly it cannot be deemed to support his notion that the kinæsthetic impressions of writing movements are not registered in a definite part of the cerebral cortex, and that this cortical region is not called into activity during the act of writing. That such impressions must be definitely registered in the cerebral cortex seems to me a self-evident truth.

It is, however, altogether another question, and one which does seem open to discussion, whether the cortical centre in which the sensory impressions produced by writing movements are registered exists altogether apart, or whether its structural elements are inextricably mixed up with others pertaining to less special movements of the hand and arm. If there is a completely separate seat of registration, destruction of such a centre should produce loss of the power of writing, independently of paralysis of other less special movements of the limb. If otherwise, the loss of power of writing from damage to the cortical region in which its kinæsthetic impressions are registered would never be able to occur alone, but would always be merged in a more general paralysis of the limb. In other words, no agraphia of this type would be recognisable as such; it would not be looked for, because the co-existing paralysis of the hand and arm would naturally be supposed to be, and would in fact be, a sufficient cause of the inability to write. On the whole it must, I think, be said that no actual proof has yet been given that the centre for writing movements is topographically distinct—in other words, that Exner's or any other separate localisation of such a centre has yet to be definitely proved. The evidence that I have previously cited, though it has been sufficient to discountenance the idea that destruction of Broca's centre of itself gives rise to agraphia, has no pretence to be adequate for the localisation of a separate centre, and the cases that have hitherto been cited in support of Exner's localisation are all of them open to very legitimate objections. There is, for instance, a case recorded by Bar[29] in which an isolated lesion existed in the foot of the second frontal convolution, but, instead of giving rise to agraphia only, there were aphasia and agraphia, and the agraphia was not total (as it should have been if a topographically separate centre for writing had been destroyed, since the patient's penmanship was good); and, though he could not express his ideas either in writing or in speech, he wrote over and over again a certain phrase or word. This case, therefore, though cited by Exner in favour of his localisation, seems to mededicedly opposed to it. Another case, recorded by Henschen,[30] has been cited as favouring Exner's localisation, which has, however, no real value. Here the patient suffered from word-blindness and agraphia, and after death there was found not only a destruction of the foot of the second frontal, but also a softening which destroyed the angular gyrus.

A third case has been recorded by J. B. Charcot and A. Dutil,[31] and is thought by Pitres to favour Exner's localisation. Here the patient was a woman sixty-four years of age, who twenty-nine years before her death had a slight cerebral attack which left her completely agraphic. Subsequently she had three other attacks, which led

Hosted by Google

successively to embarrassment of speech, left hemiplegia, and finally to pseudo-bulbar paralysis. The agraphia persisted throughout her life without appreciable diminution. She could copy letters and figures after a fashion, but was absolutely unable to write spontaneously. There was no word-blindness or word-deafness. At the necropsy five small foci of softening were found in the right hemisphere and two in the left hemisphere, one of the latter being situated exactly in the foot of the second frontal convolution.[32]

Then, again, one of the causes which led Déjerine to deny the very existence of a centre for writing movements seems to have been based upon the characteristics of two cases that were brought forward by Pitres, and which, upon the basis of his authority, have been commonly cited by others as affording evidence of the correctness of Exner's localisation. They were cases in which the patients were unable to write spontaneously or from dictation, and yet were able to copy writing. If the centre is destroyed, says Déjerine, the possibility of executing any kind of writing should be abolished. That at first sight seems perfectly true; and it may be a valid criticism against Pitres for quoting any such cases as instances of "motor agraphia."[33] But Déjerine and his followers have overlooked the possibility that Pitres may not have been quite correct in his interpretation of these cases—in which there was no necropsy. They have not recognised the fact that this particular combination of symptoms may be present without the existence of what is called "sensory aphasia" in any of its forms. It can be shown, however, that such a combination of symptoms may be easily explained by a cutting across of the audito-visual commissure that transmits impressions from the auditory to the visual word-centre (Fig. 3, *b*). This I believe, after careful

FIG. 3.

study of his memoir, to be the explanation of the partial agraphic defects in the two well-known cases cited by Pitres as examples of the effects produced by damage to the cortical centre for writing movements.[34] It is obvious that damage to the commissure above mentioned would be capable of preventing the passage of stimuli from the auditory to the visual word-centre such as would be necessary in writing spontaneously or from dictation, whilst it would leave the power of copying writing intact so long as the visual word-centre, the commissure connecting it with the writing centre, and this centre itself remained undamaged.

At present, then, it would seem that there are no uncomplicated cases of agraphia upon record produced by a small lesion in the cheiro-kinæsthetic centre, or of agraphia as an isolated symptom certainly resulting from damage to some part of the visuo-kinæsthetic commissure. It seems clear, however, that if the centre for writing is topographically distinct, complete agraphia—that is, an inability to write spontaneously from dictation or to copy with anything like facility—should be producible in either of these ways, and that in each case the disability would be uncomplicated with word-blindness, whilst there would be nothing to prevent the patient learning to write with his left hand.

The reason for this extreme rarity of agraphia as an isolated symptom doubtless is that often in what might otherwise have been a simple case of inability to write this very special disability becomes hidden and unrecognisable, owing to the lesion being large enough to cause paralysis of many other movements in the hand and arm. Thus the mere inability to write is hidden by the production of a partial brachial monoplegia. No similar causes intervene to obscure the recognition of simple, uncomplicated aphasia, and yet it must be borne in mind that even this is decidedly rare.

If, then, there are no simple, uncomplicated cases of agraphia that can be quoted, either from disease of the cheiro-kinæsthetic centre or from damage to the commissure between it and the visual word-centre, all that can be done is to cite some of the best instances available in which agraphia has been associated with aphasia, but where the former defect has been more marked than the latter. This was, in fact, the class of cases originally described by William Ogle in his paper on "Aphasia and Agraphia." One of his examples (in which there was no necropsy), where right hemiplegia with aphasia was succeeded by a condition in which amnesia and agraphia were marked, still remains one of the most typical of this kind that can be cited. But two simpler and more typical cases have been recorded by Broadbent[35] to which I would first direct attention. One of them is notable also on account of the remarkable amount of intelligence and energy displayed by the patient, notwithstanding her very defective speech and inability to write. The following is an abstract of this important case.

CASE 13.—A lady, aged about seventy years, had an apoplectic attack on July 26th, 1867. She remained unconscious for nearly twenty-four hours, and was then found to be hemiplegic on the right side and quite speechless. After two or three months she had "quite recovered the use of her limbs and regained a few words." Her relatives treated her as if she were utterly incapable of looking after her own affairs, and especially of taking charge of her own money. This was a great grievance, and when her husband's relatives visited her she tried to make it known by showing her purse and repeating excitedly, "Oh, shameful! shameful!" She had an intense dislike to her attendant, and when she left the room would often look in the direction in which she had gone, shaking her head and exclaiming with great energy, "Oh! nasty! nasty!" following it up by a long story in which there was not a single word intelligible. At length she went to live near her husband's relatives. "A house was now taken and furnished for her, and she showed herself quite competent in making all arrangements about it, and when settled in it with a new housekeeper she seemed quite contented. Her principal topic of attempted conversation for several months was her niece's and brother's bad behaviour to her. She laboured hard to make the friends among whom she now was understand her grievances. She would point out her relatives' names or refer to their letters, or in some other way show to whom she referred, and then in great excitement would exclaim, 'Oh, shameful! shameful!'; then she would turn over letters and newspapers, and when she had tried in vain for hours to convey what she wished she would shed tears and say, 'Oh, pity! pity!' At length her banker's pass-book was obtained from her niece, and she scarcely knew how to express her joy. 'I tried, and I tried,' she said over and over again. But there was still something she wished to explain, and one day, while trying very hard as usual, she made the figures 40 quite distinctly, and it was understood at last that it was something about £40; but it was not till a friend came to see her and this happened to be mentioned that it was discovered she had put £40 into a bank before her attack, and believed her niece had the acknowledgement of it, and some promissory notes with other papers. These she wished to be sent for, and eventually they were obtained. This was nearly a year after her removal, and all the time she had persevered in her attempts at an explanation. During the same time she had been making a new will, and week after week would have her sister-in-law to write out the different clauses. It often took a long time to do it to her satisfaction, but she never rested till every particular was exactly as she wished it; when the right guess was made she showed her satisfaction quite unmistakeably by her gestures, and by saying, 'Yes, yes, that's it.' . . . . That she knew what word she wanted was shown by her resorting to letters and sometimes to a dictionary; and in one of my visits, wishing to recommend a linseed-meal poultice and failing to convey her meaning, she went for the housekeeping book and found an old entry of linseed-meal. She also pointed out to me newspaper paragraphs which interested her. She frequently read, but preferred being read to. . . . . She was quite unable to write or even to sign her name. She once wrote down the figures 40, as related, and sometimes wishing to divide money would make the proper number of marks to indicate the amount of a share." On Aug. 7th, 1871, she had another apoplectic attack, after which she was

[32] Two other cases which have been cited as favouring this localisation, namely—one by Balzer (Gazette de Médecine de Paris, 1884, p. 97) and another by Shaw (Brit. Med. Jour., February, 1892)—have in my opinion no value in this connexion.

[33] Pitres attempts to get over the difficulty standing in the way of his interpretation arising from the fact that the patients were able to copy writing in the following manner. He says (Congrès Francais de Médecine Interne, 1894, Rapport sur la Question des Aphasies, p. 10): "Copier, en effet, est toute autre chose qu'écrire couramment. C'est un acte de motilité générale qui n'a pas de centre d'exécution spécialisé, pas plus d'ailleurs que l'acte de tracer sur le sol avec le bout de sa canne, ou avec le pied, des traits ayant la forme de lettres. Ces actes là impliquent une attention soutenue, une surveillance constante de l'esprit, qui manque absolument dans l'écriture courante. C'est pourquoi l'agraphique dont les membres supérieurs ne sont pas paralysés, peut encore copier, bien qu'il ne soit plus capable d'écrire spontanément."

[34] Revue de Médecine, 1884, p. 864. These cases are also quoted more briefly by Wyllie (loc. cit., p. 357), though in the first of the two cases he omits the very important detail that the patient was able to copy writing easily.

[35] Transactions of the Royal Medical and Chirurgical Society, 1872, pp. 146 and 160.

Hosted by Google

found to be paralysed on the left side. She died on Aug. 12th, and at the necropsy no cause for the last apoplectic seizure was found, but two old apoplectic cysts were discovered in the upper border of the fissure of Sylvius. One "which might hold a nut" was in the situation at the lower end of the ascending frontal gyrus, "and a very small part of the adjacent posterior end of the third or inferior frontal gyrus." "Again, in the supra-marginal lobule over the posterior end of the fissure of Sylvius was another hollow filled with connective tissue, and when the fissure itself was opened out it was found to contain at this part a super-abundance of connective tissue, and the convolutions of the posterior end of the island of Reil were completely atrophied." There was some atrophy also of the tail of the intra-ventricular portion of the corpus striatum.

In addition to the evidences of intelligence and energy displayed by this patient, there is also the fact that there was no alexia associated with the aphasia and agraphia. The latter defect was much more marked than the former; and the fact that the patient could use more words and sentences than are customary may perhaps be explained by the small extent of the lesion in the left third frontal gyrus. Although the paralysis of the right upper extremity had been quite recovered from, the agraphia was absolute. The posterior extremity of the second frontal gyrus was uninjured, but the posterior of the two old focal lesions discovered would probably have destroyed the commissural fibres between the visual word-centre and the cheiro-kinæsthetic centre not far from the former of these centres. In the next case there was a very similar inequality between the ability to speak and the ability to write.

CASE 14.—A German, aged thirty-four years, was admitted into St. Mary's Hospital in February, 1870. He had suffered from rheumatic fever in 1885. On the 4th he fell off his stool whilst at work. Two days after he was found to have lost the use of his right hand and arm and to be unable to speak. On the evening of the 8th he was brought to the hospital, and was then found to be partially hemiplegic on the right side and unable to answer questions intelligibly. He soon began to improve, and Broadbent's notes on the 14th are as follows: "All his answers in a low, smooth tone, without modulation of voice; he could not be induced to utter loudly even a word he could say. Answered 'Yes' and 'No'; told me his age correctly and his name, but indistinctly. Asked how he is replies, 'Better' or 'Quite well,' rather indistinctly. If he had pain in the head since the attack? 'No.' Before? 'Yes, wonderful.' If he slept well? 'Nicht'. . . . (something or other which could not be made out). If appetite good? 'No' . . . It was impossible to understand him when he attempted a phrase or when he tried to say anything to which I had no clue." A strong German accent was distinguishable in all he said, whereas before the attack he spoke English particularly well. "A peculiarity of his attempts to read or speak was his persevering effort to master a word, syllable by syllable, by trying on and on again. For example, when asked to read the words 'diet-card' his attempt was something like this, 'Diget, dicht, dite, dite, dite car.' The next moment he pointed to his name, saying, though not very distinctly, 'Dat my name.' Up to this time and a week later, Feb. 21st, he could not sign his name or write the simplest word, such as 'yes' or 'no,' when asked to do so, or copy a word pointed out to him." He remained in the hospital some weeks longer, improving very slowly, and before he left he could "with great effort write his name."

Nothing can be said as to the situation of the lesion here or in the next case, which is the best of those which William Ogle was able to bring forward in his paper. We must be guided only by the clinical facts recorded.

CASE 15.—James Simmonds, aged fifty-four years, after a heavy blow on the left side of the head, seven years ago was obliged to give up his work. He spoke without difficulty or hesitation, but miscalled things strangely. He then had a fit one morning whilst dressing, which left him speechless and hemiplegic on the right side. For a fortnight he could not speak at all, though he was quite sensible. He could not say so much as "Yes" and "No." From this he gradually recovered, but always, as before, miscalled things. . . . A month ago he had a second fit, which left him with less power than before in his right side, but made little or no change in his speech. There is now partial paralysis of the right side, which does not prevent his walking. The facial muscles on that side are slightly affected as well as the limbs. His speech is very hesitating and imperfect. He often stops suddenly at a loss for a word and then frequently uses a wrong one, as, for example, he substituted "barber" for "doctor," "two-shilling piece" for "spectacles," "winkles" for "watercress." He can, however, pronounce any word perfectly when prompted. He says that he generally knows when he has used a wrong word, but not always. Before his illness he wrote a good hand and was above his lot as regards education. Now he cannot form a single letter. Even with a copy before him he makes only uncertain up-and-down strokes. I gave him some printed letters and asked him to pick out his name. After a long time he arranged JIOMNOS. Clearly he had some slight notion of the letters which composed his name. According to his wife, before his illness he spelt well, and was very particular about the spelling of his own name, which is one admitting of many variations. When a copy was before him he quickly picked out and arranged his name correctly. He can read; but he says that reading makes him very giddy and causes great pain in the head. His general understanding seems good and up to the average of men in his class.

The conditions here recorded represent the remainders of an attack of aphasia, as it would seem that the amnesia was perhaps not much more than had previously existed. We may conclude that in this case also the most severe or durable lesion was in the track of the commissural fibres between the left visual word-centre and the cheiro-kinæsthetic centre (Fig. 3, *d*), but that in all probability there was also some damage to the former word-centre itself. This latter defect is indicated from the difficulty he had in spelling his name with separate printed letters placed before him; for inability to spell—that is, inability spontaneously to recall the letters composing a word—probably depends in the main upon some defect in the visual word-centre, and although he could read, what is said seems to imply that his powers were perhaps not great in this direction. It is therefore by no means a clear case, but one in which the defects were somewhat mixed.

Although we are unable as yet to cite any simple uncomplicated case of agraphia due to disease in the posterior part of the second left frontal convolution, yet, according to Binet and Fere,[36] it is easy to produce agraphia by suggestion in hypnotised persons. Speaking of their experiments Ballet[37] says: "They show that the loss of the motor memory for writing is of the same order as the abolition of other motor [kinæsthetic] memories, such as those which preside over the ability to smoke, to sew, or to embroider. For each of these acts which we are accustomed to perform there exists, in fact, a motor memory, so much the more easily disturbed, in all probability, as the acts themselves are more complicated and require more delicate muscular combinations. As an example of motor amnesia connected with special movement associations I may recall a curious case related by M. Charcot in one of his lectures: it was the case of a player on the trombone who had lost the memory of the associated movements of the mouth and of the hand necessary for playing on the instrument. All the motor memories in this patient were intact save this one. This musician had forgotten how to handle the trombone, as others had forgotten how to handle the pen." If we substitute in the above-quoted passage for "motor memory" the term "kinæsthetic memory" we may believe the loss of the different kinds of kinæsthetic memory referred to, which can be brought about in hypnotised persons, must be due to a temporary functional inertia produced under the influence of suggestion in the several parts of the general kinæsthetic centre in relation with this or that movement.

It seems best now, at the close of our discussion concerning aphasia and agraphia as combined and separate symptoms, to enumerate in tabular form the different modes in which complete or partial agraphia may be produced. Although I shall thus be anticipating results subsequently to be developed, it will be advantageous to show now how other different forms of agraphia are to be distinguished from those we have been considering and from one another.

AGRAPHIA.

Complete.	Uncomplicated.	1. Destruction of the cheiro-kinæsthetic centre.
		2. Destruction of the visuo-kinæsthetic commissure.
	Complicated with word-blindness.	3. Destruction of the visual word-centre.
Partial.	No spontaneous writing or from dictation, but can copy; no word-deafness.	4. Destruction of the audito-visual commissure.
	No spontaneous writing, or from dictation, but can copy; word-deafness present	5. Destruction of the auditory word-centre.
	Can write spontaneously or from dictation, but cannot copy; word-blindness present.	6. Destruction of the visual word-centre (in some educated auditives).
		7. Isolation of the visual word-centre from all afferent fibres.

The supposition is that in the large majority of cases the various lesions that have been above referred to as causes of complete or partial agraphia will be in the left hemisphere in right-handed and in the right hemisphere in left-handed persons. Of these various forms Nos. 1, 2, and 7 should occur in all individuals alike, in association with the lesions named; but Nos. 3 and 6 are two degrees of agraphia that may be met with in association with word-blindness according as the individuals in whom the lesions specified occur are "visuals" or strong "auditives" much accustomed to write. On the other hand, Nos. 4 and 5 are two cases in which the same degree of agraphia may be met with, but differing by the absence of word-deafness in the one case and its presence in the other. I say *may* be, because such symptoms might not occur in a strong "visual." It will be observed also that each of the partial forms of agraphia

except the first is associated either with word-deafness or with word-blindness.

DEFECTS IN THE AUDITORY AND IN THE VISUAL WORD-CENTRES.

Since the publication in the year 1874 of an important memoir by Wernicke entitled "Der Aphasische Symptomen-complex," it has been the fashion to speak of the defects of speech due to lesions in the auditory and the visual word-centres as "sensory aphasia," in contra-distinction to that produced by damage to Broca's region, which, in accordance with then prevalent notions, was and has since been very commonly spoken of as "motor aphasia." This mode of distinguishing these defects, though it has a certain convenience and has been widely adopted, is not in accordance with my views, as I hold the latter to be as much a sensory region of the brain as the former. It would, I believe, be much better if the term "aphasia" were restricted to the defects of speech produced by lesions in Broca's region, and the term "aphemia" to those dependent upon sub-cortical lesions in the course of the pyramidal fibres, leaving the speech defects produced by lesions of the convolutions around the posterior extremity of the Sylvian fissure to be grouped as so many varieties of "amnesia." Under this latter generic name would be included many forms of speech defect due to defective recall of the auditory and the visual images of words, and produced either by lesions of the auditory and the visual word-centres themselves or of the commissures by which they are united to one another and to corresponding centres in the opposite hemisphere. In all these cases there would be more or less interference with the recall of auditory and visual images of words. And whether we call the case one of sensory aphasia or of amnesia, in each instance alike the precise degree and nature of the defect or defects would have to be settled by a systematic examination, so as to determine whether we had to do with mere diminished recollection of words, with complete loss of their auditory or visual images, or with other combinations of symptoms pointing either to partial isolation of these centres from one another or to isolation from the general auditory or visual word-centres of which they form part. It is true that such a nomenclature involves a slight inconsistency, seeing that aphasia and agraphia are also, in accordance with my views, forms of amnesia due to the non-revival of glosso-kinæsthetic and cheiro-kinæsthetic images respectively. But these kinæsthetic images, as I maintain, play only a small part in thinking processes, and neither of them is subject to independent conscious recall like the auditory and visual images of words which constitute our habitual thought counters. The inconsistency is, moreover, much less than that which is entailed by speaking of "motor aphasia" and "sensory aphasia," as though the former belonged to a radically different category and really depended upon the lesion of a motor centre. The advantage would be great of confining the term "aphasia" to its original signification, and not including under it various types of speech defects which are radically different in nature and produced by lesions in totally different cerebral regions; this is especially desirable when the objectionable generic term "sensory aphasia" can be replaced by another having a very similar general connotation.

It has been commonly supposed, and repeated over and over again by workers in Germany and France, as well as by those writing in our own language both here and in America, that Wernicke was the first to call attention to and explain that form of speech defect that is now known as "word-deafness," this particular name having been given to the condition shortly afterwards by Kussmaul. It is admitted that the companion defect of the visual centre now known as "word-blindness" had been previously recognised by several writers, though it had not been clearly explained; but "word-deafness" was supposed to have escaped observation by writers on speech defects, the individuals suffering from it having been previously thought to be insane, or at least demented.[38]

The merit, however, of having determined the region of the brain at fault in cases of word-deafness (viz., the hinder half of the upper temporal convolution, with perhaps a portion of the hinder extremity of the middle temporal convolution) clearly belongs to Wernicke; though, as I shall subsequently endeavour to show, he was far from correct in saying that the complex of symptoms resulting from such a lesion was word-deafness, paraphasia, alexia, and agraphia. This view as to the symptomatology of the lesion was founded upon too narrow a basis of observed cases with necropsies. A wider experience and knowledge now necessitates its complete revision.

That it is not correct, however, to say that word-deafness and word-blindness were not well understood till Wernicke defined their nature may be shown by the following quotation from my paper "On the Various Forms of Loss of Speech in Cerebral Diseases," published in 1869:—[39]

"Most aphasic patients can *understand perfectly what is said* to them and can follow and feel interested when they hear others read aloud. In these cases we may presume that the afferent fibres connecting the auditory centres of the medulla with the auditory perceptive centres of the cerebral hemispheres, and also these latter centres themselves, are intact, so that the spoken sounds revive their accustomed impressions in the hemispheres, these being perceived as words symbolic of things or ideas, which, being duly appreciated by the individual as they are conjured up, suggest to him the thoughts which they are intended to convey. In certain of the severe cases of aphasia, however, as in that noted by Dr. Bazire, recorded at p. 16, and in Dr. Gairdner's case (Glasgow Medical Journal, May, 1866, p. 13, and Transactions of the Philosophical Society of Glasgow, 1866), it is distinctly stated that the patient either did not gather at all, or with difficulty and imperfectly, the import of words when he was spoken to, though he could be made to understand with the utmost readiness, by means of signs and gestures. Must we not suppose in such a condition either the communication of the afferent fibres with the auditory perceptive centres is cut off, or that this centre itself, in which the sounds of words are habitually discriminated and associated with the things to which they refer, is more or less injured? In either of these cases, though the sound is not appreciated as a *word* having its definite meaning, we must not expect that there would be deafness; the sound would be still heard as a *mere sound*, only it does not call up that superadded intellectual discrimination by the ingrafting of which upon it it can alone be made to serve as a symbol of thought. Hence the individual does not adequately comprehend when spoken to, though he may be quite capable of receiving and appreciating fully the import of signs and gestures which make their impression upon his visual perceptive centres. . . . . And where the individual *cannot read* I am inclined to think this must be owing either to some lesion of the afferent fibres to the visual perceptive centre, of the visual perceptive centre itself, or of the communications between the cells of this centre and those of the auditory perceptive centre. If lesions existed in either of the first two situations the visual impression could not receive its intellectual elaboration, and consequently it could not call up its associated sound (word) in the auditory centres, and hence no meaning would be conveyed by the hieroglyphic marks of the printed or written pages. They would be to the person mere meaningless strokes, just as we have assumed that if similar defects existed in the auditory perceptive centres, or in the afferent fibres with which they were connected, the individual could not appreciate the meaning of spoken words—these would be to him mere sounds."

At the date when this paper was written I knew nothing about what I now term "kinæsthetic centres" and had not fully realised the importance of kinæsthetic functions. At this period, moreover, the notion that definite "motor centres" exist in the cerebral cortex had not been mooted. This explains the reason of the absence of any reference to the needed activity of kinæsthetic centres in the above quotation.

Turning now to the question of the symptomatology of the condition named "sensory aphasia" by Wernicke, and referred by him to a lesion of the posterior extremities of the upper and middle temporal convolutions, it should be observed that Kussmaul shortly afterwards broke up into two sets of symptoms what were originally described as a single group by Wernicke. According to Kussmaul, what he first termed "word-deafness" is the primary and essential result of destruction of the hinder extremities of the upper temporal convolutions; while what he termed "word-blindness" holds a similar essential relationship to destruction of the angular and parts of the supra-marginal gyri. This is the view now commonly held, and both varieties are spoken of as forms of "sensory aphasia," though Wernicke's original doctrine as to the very complex results of a lesion in the auditory word-centre is held at the present day by Dójerine as well as by Mirallié. They both speak of word-deafness, paraphasia, alexia, and agraphia as the results of such a lesion.

It must be admitted that the functional relations of the auditory and the visual word-centres are so intimate, and their sites so close to one another, that a lesion occupying the one is apt more or less to interfere with the functions of the other for a longer or shorter period, which may vary with the nature and abruptness of the lesion, as well as with the different endowments of individuals. Disturbance to a very marked extent of the functions of the visual word-centre as a result of a lesion in the upper temporal convolutions is,

[38] This statement has been repeated by Wyllie in his recently published work on the Disorders of Speech (p. 295), although de Watteville had previously pointed out in Brain (1885, p. 267) that I had five years before the appearance of Wernicke's memoir fully appreciated the nature of the defect as well as that of "word-blindness."

[39] British and Foreign Medico-Chirurgical Review, 1869, pp. 40 and 42.

however, by no means so universal as Wernicke's and Déjerine's statements as to the symptomatology of this lesion would imply. Thus, out of sixteen recorded cases of "sensory aphasia" in which the lesion was pretty closely limited to the hinder part of the first and more or less of the second temporal convolutions, in only five of them is there any mention of the existence of some amount of word-blindness. Doubtless had the patients been studied more minutely (after the manner practised by Thomas and Roux[10])

FIG. 4.

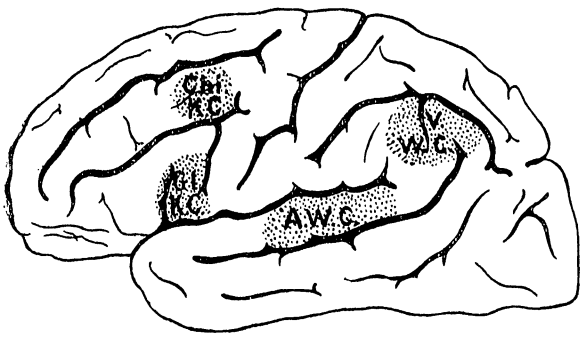

Diagram showing the approximate sites of the four word-centres in the left cerebral hemisphere.

some minor amounts of word-blindness might have been found in others; but that is not what Wernicke meant, and is not other than what might be expected if we look to the close functional and topographical relations of the two word-centres.[11]

It will subsequently be shown, moreover, that paraphasia is met with in only a little more than one-third of these cases, so that Wernicke's "symptomencomplex" does not prove to be at all in accordance with the data at present available, although his views are still adhered to by Déjerine and Mirallié.

It must, indeed, be admitted that the defects in the auditory and the visual word-centres giving rise to word-deafness and word-blindness respectively may occur separately or together, and in the latter case the defective action in the two centres may be unequally developed. Hence the very marked clinical variations that are met with as a result of lesions in the convolutions surrounding the posterior extremity of the Sylvian fissure. Another cause of clinical variations, even with similar lesions, is perhaps to be found in the different degrees of education of the persons attacked, and their consequent greater or less facility in reading and writing. Still another cause of variability is to be found in the varying individual endowments of patients in regard to the relative activity of their different word-centres—in other words, according as the patients are marked "auditives" or "visuals" respectively. Connate individual variations of this kind may give rise to notable clinical differences, even as results of similar lesions.

All that can be done here, therefore, is to point out the most common combination of symptoms, dealing with the various parts of the subject in the following order: (1) defects resulting from abnormal conditions of the left auditory word-centre; (2) defects resulting from destruction of the auditory word-centres in each hemisphere; (3) defects resulting from destruction of the auditory and the visual word-centres of each hemisphere; (4) defects resulting from isolation of the left auditory word-centre; (5) defects resulting from abnormal conditions of the left visual word-centre; (6) defects resulting from isolation of the left visual word-centre; and (7) defects resulting from combined lesions of the left auditory and visual word-centres, together with some remarks on the condition which has been named "psychical blindness" or "object blindness."

1. DEFECTS RESULTING FROM ABNORMAL CONDITIONS OF THE LEFT AUDITORY WORD-CENTRE.

Of all the word-centres the integrity of the auditory is of the most importance, and the defects due to different degrees of functional disability therein are the most varied, because this is the centre in which in the great majority of individuals words are first revived during thought, whether this be silent or whether it constitute the first stage in the processes of speaking or of writing. The effects of functional degradation or of partial damage to this centre may be considered first, and afterwards those resulting from its complete destruction.

(*a*) *Effects produced by functional degradation or partial damage of the left auditory word-centre.*—In the slighter degrees of damage and functional degradation we have to do with the most typical forms of verbal amnesia, in which various words fail to be recalled as they are needed in ordinary speech. The term "amnesia verbalis" applies especially to this defect, and the objections that have been raised to it on the ground that loss of auditory images constitutes only one kind of verbal amnesia are of no practical value because the two kinds of kinæsthetic images are, as I maintain, not spontaneously revivable as primary thought counters, and because it is only in rare cases that visual images of words are primarily revived. The term "amnesia verbalis" is therefore especially applicable to this particular functional disability of the auditory word-centre.

This failure to recall words is always most marked with the names of persons, places, and things, these being the most specialised units of speech. The most familiar type of this defect is that which occurs as a result of defective nutrition, either with advancing years or during convalescence from prostrating diseases. Such persons are often noticed to halt in their speech, owing to their inability to recall some such words. Occasionally, however, a similar or more marked defect of the same order occurs as a result of some more or less distinct lesion of the brain. A good example of amnesia of this type, where the "volitional" recall of names was impossible though their "sensory" recall was preserved, is thus referred to by Trousseau in his "Lectures."[12]

CASE 16.—"The patient does not speak because he does not remember the words which express ideas. You recollect the experiment that I often repeated at Marcou's bedside. I placed his nightcap on his bed and asked him what it was. After looking at it attentively he could not say what it was called, and exclaimed, 'And yet I know well what it is, but I cannot recollect.' When told that it was a nightcap he replied, 'Oh! yes, it is a nightcap.' The same scene was repeated when various other objects were shown to him. Some things, however, he named well, such as his pipe. He was, as you know, a navvy, and therefore worked chiefly with the shovel and the pickaxe, so that these are objects the names of which a navvy should not forget. But Marcou could never tell us what tools he worked with, and after he had been vainly trying to remember, when I told him it was with the shovel and the pickaxe, 'Oh! yes, it is,' he would reply, and two minutes afterwards he was as incapable of naming them as before."

As Lichtheim points out,[13] evidences of amnesia are "more easy to demonstrate when the patient is made to name objects than when he is engaged in ordinary talk; names which occur without effort in fluent speaking arrest him when he has to find them for objects or persons shown to him." There is general agreement as to the fact that in amnesia words are lost in a tolerably definite order. First there are failures in the recall of proper names, then of other nouns; and only much more rarely of verbs, adjectives, and pronouns. Of this fact different explanations have been given. I will quote two of the best. Kussmaul says:—[14]

"The more concrete the idea the more readily is the word to designate it forgotten when the memory fails. Probably the only reason for this is that the conceptions of persons and things are more loosely connected with their names than the abstraction of their circumstances, relations, and properties are. We easily represent persons and things to ourselves without names; the image of sense is here more important than the symbol—i.e., the name—which conduces but little to our comprehension of personages or objects. More abstract conceptions, on the contrary, are attained only with the aid of words, which alone give them their exact shape. Hence verbs, adjectives, pronouns, and, still more, adverbs, prepositions, and conjunctions, possess a much more intimate relation to thought than nouns. We can conceive that the processes of

[10] Bulletin de la Société de Biologie, 22 Février, 1896.

[11] The cases to which I refer where the lesion has appeared to be pretty completely limited to the hinder part of the first or of the first and second temporal convolutions are those which in Mirallié's list (De l'Aphasie Sensorielle, 1896, p. 135) are numbered, 1, 3, 4, 6, 7, 10, 12, 14, 19, 21, 25, and 32; together with those in Amidon's list (New York Medical Journal, 1885, pp. 113 and 181) numbered 7, 14, 17 and 18. Of these, the five cases in which some amount of word-blindness co-existed are those which in Mirallié's list are numbered 12, 14, 19, 21, and 25. In Amidon's No. 11, moreover, there was the co-existence of aphasia and word-deafness, owing to simultaneous lesions in Broca's region and in the upper temporal convolutions; nevertheless the patient showed neither alexia nor agraphia. I have purposely alluded to these two lists, which include, I believe, almost all the complete cases with necropsies of "sensory aphasia" hitherto published (many of them being included in both lists), because they are both fairly accessible, and a reference to them will thus enable anyone interested in the matter to verify the correctness of my statements and criticisms with comparative facility.

excitation and the combinations in the cellular network of the cerebral cortex must be much more numerous for the creation of an abstract than of a concrete conception, and that the organic tracts which connect the former with its name must be correspondingly much more numerous than those of the concrete."

The other explanation, which may be considered as supplementary to, and not incompatible with, Kussmaul's, is that which was given by Ross. He said:—[45]

"The science of language teaches unmistakeably that the language of aboriginal man consisted almost entirely of verbs, demonstrative pronouns, and a few adverbs of time and place, and that the names of even common objects are always derivative, and consequently of much later growth than the roots themselves, and it is only what might have been expected that in the dissolution of language caused by disease nouns should disappear from the vocabulary of the patient before the parts of speech which have been first developed, and therefore most deeply organised."

In the slighter forms of amnesia the efforts at recollection of a person who is "at a loss for a word" tend also to call the visual word-centres into an incipient activity. Graves[46] placed on record an excellent illustration of this fact, though he quotes the case merely as "a remarkably exaggerated degree of the common defect of memory observed in the diseases of old age, in which the names of persons and things are frequently forgotten, although their initials are recollected."

CASE 17.—"The man was a farmer, fifty years of age, who had suffered from a paralytic attack, from which he had not recovered at the time of observation. The attack was succeeded by a painful hesitation of speech. His memory was good for all parts of speech except noun-substantives and proper names; the latter he could not at all retain. This defect was accompanied by the following singular peculiarity: he perfectly recollected the initial letter of every substantive or proper name for which he had occasion in conversation, though he could not recall to his memory the word itself. Experience had taught him the utility of having written on manuscript a list of the things he was in the habit of calling for or speaking about, including the proper names of his children, servants, and acquaintances; all these he arranged alphabetically in a little pocket dictionary, which he used as follows: if he wished to ask anything about a cow, before he commenced the sentence he turned to the letter C, and looked out the word 'cow,' and kept his finger and eye fixed on the word until he had finished the sentence. He could pronounce the word 'cow' in its proper place so long as he had his eyes fixed upon the written letters; but the moment he shut his book it passed out of his memory and could not be recalled, although he recollected its initial and could refer to it when necessary. He could not even recollect his own name unless he looked out for it, nor the name of any person of his acquaintance; but he never was at a loss for the initial of the word he wished to employ."

The fact, moreover, that in those cases where we cannot "get out" a particular word we often seem to know something of its length, and can say that it consists of about so many letters, also seems to testify to an abortive revival of the word in the visual centre. But the fact that this partial revival is not associated with full consciousness of the word and does not enable it to be written is one of considerable significance, because it seems to show how all-important in the majority of cases is the primary revival in the auditory centre, not only for the accomplishment of speech, but also for that of writing, the visual word-centre being probably called into play in writing spontaneously as well as in writing from dictation through the intermediation of the auditory word-centre.

It seems reasonably certain that in the great majority of cases in reading aloud there is first the excitation of the visual word-centre, then the passage through commissural fibres of stimuli to related portions of the auditory word-centre before the stimulus passes on to the glosso-kinæsthetic centre.[47] This affords the explanation of another peculiarity in the class of cases of which we have been speaking, as well as of others in which the amnesia has been even more profound. Many cases have, in fact, been recorded in which the patients' speech has been so disordered that they could scarcely say more than three or four consecutive words, and could perhaps utter no nouns; yet when a book is placed before them they are capable of reading aloud correctly and with ordinary facility. I have seen three such cases. One of them was a typical instance, and the following are some details concerning it.

CASE 18.—A lady, aged eighty-one years, had a slight stomach derangement, followed by diarrhœa, in the spring of 1885. She had been rather deaf for many years, but after this slight illness an amnesic difficulty in speech very gradually became more and more pronounced, and after about eighteen months became associated with marked paragraphia. Two years after the commencement of this speech trouble I found this patient capable of understanding all that was said to her in a sufficiently loud and distinct voice. She was thoroughly capable, also, of superintending her household affairs, correct in her accounts, and always knew exactly what change she ought to receive after having given money for the purchase of food or other necessaries. She made use of brief sentences, generally stopping short when she came to a noun, or she would then substitute the word "things" for any such part of speech. Thus, she said, "I will go up and see what we can," meaning that she would go upstairs and see what she could find; or "Will you have the things?" meaning some refreshments for a journey. At this time she was accustomed to read novels with large print for several hours daily. I found that she could read aloud as well as ever, and she did actually read to me, with only two or three slight mistakes in pronunciation, nearly half of a column of a newspaper. I was able to satisfy myself, also, that she understood the meaning of what she was reading; her laughter when I gravely gave her a short amusing paragraph to read left no doubt as to this point. During the next six months her condition became steadily but markedly worse. Here is a letter written to her son about the end of June, in which for the first time she omitted to put the name of the month and his Christian name at the commencement of the letter. "29, -87.—MY DEAR PAPA.—I hope you are well, and think you are well for something for the Queen, and too things for the Queen [evidently referring to two papers which had been sent to her with details of Jubilee proceedings.] Pills for the father [an intimation that she wished some pills to be sent to her.] I hope you are well.—Yours affectitory." [The surname was spelt wrongly; she had previously always signed with the Christian name alone.]

Here are a few details concerning another of these cases, in which, however, the amnesia was much less severe.

CASE 19.—A lady, aged sixty-five years, was sent to me on Feb. 18th, 1893. She had had no fit of any kind, and no pains in the head—only a feeling of "confusion in the occiput" for several years. She had suffered much from throat affections in early life, and there had been some deafness for nearly thirty years, which had slowly increased. She did not hear the ticking of a watch on either side even with contact. She heard a tuning fork on both sides with contact, and also for about two inches away from the ear on each side. Her husband died four years previously; she then became weak and suffered from dyspeptic symptoms for several weeks. There was no illness after this, but eighteen months ago she began to suffer from difficulty in expressing herself. There was no defect of articulation, but a difficulty in finding words, and this trouble had become much more marked for the last five months. There had been no unilateral weakness and there is no trace of any now. She speaks in broken sentences, omitting smaller words, and is often at a loss for a noun. Articulation is distinct. She reads from a book fluently, correctly, and with no appreciable hesitation.

A good instance of this degree of lowered excitability of the auditory word-centre was also reported by Ross.[48]

Lichtheim has likewise recorded an extremely interesting case of this type. It occurred in the person of a busy medical practitioner who met with a carriage accident and was carried home unconscious. There was paresis of the right arm and leg, and he was confined to his bed for about a week. The following are some of the particulars given by Lichtheim as to the patient's condition.

CASE 20.—Speech was much affected; the first day the patient only said "Yes" or "No," but quite appositely. Gradually more and more words returned, at first imperfectly. Whilst his vocabulary was still very meagre, it was observed that he could repeat everything perfectly. Soon after the accident he began to read with perfect understanding. It was established beyond doubt that he could read aloud perfectly at a time when he could scarcely speak at all. The statements of his wife are most positive and trustworthy upon this point, though he himself does not recollect what took place just after the accident. She states that after much difficulty in making himself understood by gestures he obtained a newspaper, and to the great astonishment of all present he began to read fluently. She herself thought it most strange and inexplicable. . . . . He could not write voluntarily at all; but this faculty returned slowly and imperfectly, as did speech. On the other hand, he could, soon after he left his bed, copy and write from dictation.

The meaning of this ability to read aloud in such a case is that though the auditory word-centre is so much damaged as to be unable to act spontaneously (that is, under volitional stimuli), it is still capable of responding to the associational stimuli coming to it as a result of strong excitation of the visual centre.[49] Persons so affected are also quite capable of responding to sensory stimuli passing direct to the auditory centre itself—that is, they can at once repeat words uttered before them.

Another very interesting but more complicated case

[45] Loc. cit., p. 112.

[46] Dublin Quarterly Journal, 1851.

[47] Several of the writers on aphasia, however, in their diagrams assume that the stimulus passes direct from the visual word-centre to Broca's region (See Ballet, loc. cit., p. 164).

[48] On Aphasia, 1887, p. 40, Case 8. I am a little puzzled, however, in view of the simple explanation that can be given of this patient's defect, to find that in different parts of his work Ross describes cases essentially similar under different names—see the case of a boy referred to on p. 68 as an example of what he terms the "second degree of aphemia," and also his reference to another example (on p. 72), which he terms, after Kussmaul, "aphasia of recollection."

[49] Lichtheim's interpretation of this case (Brain, 1885, p. 447) is wholly different from mine. He accounts for it by supposing a damage of commissural fibres to exist, which pass between his postulated "centre for concepts" and Broca's convolution, which for him also is a motor region rather than one of sensory type. These are the cases which Lichtheim includes in his Type IV. A defect closely allied to this which I have just been considering has been described by Broadbent in a paper "On a Particular Form of Amnesia; Loss of Nouns" (Transactions of the Medico-Chirurgical Society, vol. lxvii., 1884, p. 249). His explanation is also more in accordance with that of Lichtheim than with mine.

Hosted by Google

illustrating the same degree of amnesia has been recorded by Dr. P. J. Cremen,[50] the essential details of which are as follows.

CASE 21.—The patient, a man of intemperate habits, was admitted to the Cork North Infirmary on April 10th, 1885. He was the subject of aortic and mitral disease, fully compensated, which had followed an attack of rheumatic fever in childhood. About October, 1883, he suddenly became giddy, with loss of speech, but no paralysis of limbs. He continued to work during the same day, and during five months his speech slowly improved very much. "He now commenced to do some light work, being able to make himself understood fairly well, occasionally using one word for another." About Christmas, 1884 on awaking one morning, he was surprised to find that he had lost the sight of his left eye. (This was subsequently found to be due to embolism of the central artery of the retina.) "He continued otherwise the same as regards speech, until about four weeks before admission, when, after a hard day's work, whilst in the act of holding a candle, he suddenly allowed it to drop and commenced to cry. His speech again became very imperfect and his face was slightly drawn, but there was no appreciable paralysis of limbs." Since then no change had taken place in his symptoms. On admission volitional speech was much affected. When asked of what he complained he pointed to his left temple and said he had a pain there, and on being asked if it was constant he said not. He also pointed to the left eye, and indicated that he could not see with it. His memory of names, places, and things was very defective. He did not recollect the names of his father, mother, or other near relatives. When asked to try, he made an effort to do so, sometimes repeating his own name instead, evidently knowing that he was wrong. When corrected, he repeated the name distinctly, having no difficulty whatever in articulation, the latter being very distinct. When asked to name the organs of sense he called the ear a "hair-pin," and named correctly the nose and tongue; he did not recollect the name of the eye, and called this also the "tongue"; but when corrected said, "Yes, eye; that's right." When further questioned he became confused, calling nearly everything that was shown to him "tongue." His vocabulary was, however, liable to variation from day to day. When asked to repeat the Lord's Prayer he failed to do so, but repeated another prayer instead; however, when given the first sentence he repeated it through correctly. His understanding of spoken and written language was perfect. He could repeat accurately and quickly words spoken before him. Notwithstanding this great defect of memory of words, he could read aloud clearly and distinctly, without hesitation, a page of a book from beginning to end. The following composition, in which it is impossible to discover any meaning, was written by him at my request as the history of his case: "Cork Molens.—I noscent nountg ani ammbys gosisbyoyey imitwats yab I bet yas you me sent sml me good me much cocleped." He wrote his own name and residence accurately, and could write numerals to any extent without dictation. The following will exemplify defects in writing from dictation. When asked to write the word "just" he wrote "fugl," for "subject" "supfect," for "speak" "sery," for "found" "spunt." Strange to say, when told to spell those words he did so accurately in every instance, and when asked why he did not write them he explained that he had forgotten how to make the letters. He remained in hospital for about three months, and left much improved in his speech, being able to carry on a conversation fairly well, though occasionally using one word for another. He could name objects better. Volitional writing was not improved; writing from dictation was slightly better.

Apart from the marked amnesia with preservation of ability to read aloud, this case is remarkable for the gibberish character of the patient's writing, combined with an ability to spell correctly—two characters that do not often go together. In this relation it may be mentioned that it sometimes happens that the speech of patients is entirely limited to a mere imitative repetition of words spoken in their hearing, while they are without the power of volunteering any statement—that is, their auditory word-centres respond only to direct sensory incitations, and not at all to those of an associational or volitional order. In these cases (usually included under the term "echolalia") a marked general mental impairment almost invariably co-exists.

A defect of this kind (occurring in a woman who was hemiplegic from cerebral hæmorrhage) has been recorded by Professor Bêhier.[51] She was born in Italy, and had resided both in Spain and France; of the three languages she had thus acquired she had completely forgotten the Italian and Spanish, and had only retained a most limited use of French. In this latter language *she only repeated like an echo* the words pronounced in her presence, without, however, attaching any meaning to them. But in the case of a woman seen at the Salpêtrière by Bateman the mimetic tendency was much stronger. She even reproduced foreign words with which she had never been familiar. It is clear that in such a case as this there must have been a mental degradation of a much wider kind than that which occurs when the auditory word-centre alone is reduced to its lowest grade of functional activity.

THE Farnham Rural District Council on April 1st granted an extra donation of £20 to the medical officer for his special services during the recent outbreak of diphtheria.

ON FUNCTIONAL MURMURS: A FURTHER CONTRIBUTION IN ILLUSTRATION OF THE MIMICRY OF ORGANIC HEART DISEASE.

BY DAVID DRUMMOND, M.A., M.D. DUB., D.C.L. DURH.,
SENIOR PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

SINCE my paper on Functional Heart Murmur appeared in THE LANCET of July 27th, 1895, I have met with a number of additional cases illustrating the difficulties attending the diagnosis of heart disease. A few of these I have selected in order to call attention once more to the frequency with which functional disturbance simulates organic mischief. The subject is of great importance, and I am the more disposed to pursue it because of the interest shown by a number of thoughtful clinical observers who noticed the paper. I ventured to refer to three varieties of functional murmur—namely, the cardio-hæmic or anæmic, the cardio-muscular or neuro-typtic (so-called), and the cardio-respiratory. To this nomenclature I am disposed to adhere, though I am quite free to admit that the explanation offered of the murmurs may not be entirely correct. In some respects the appended cases resemble closely those alluded to in my first paper; in others they differ, and chiefly in point of time that the murmurs occupy in the cardiac cycle.

CASE 1.—A man, aged fifty-two years, a life-long neurotic, who lived in dread of the development of organic disease, complained of dyspepsia, pain after food, flatulency, loss of appetite, some reduction in weight, palpitation, and a sense of general weakness. The heart rate averaged 85; the apex beat was in the fifth interspace, about half an inch to the left of the usual position. On auscultation at the apex the first sound was reduplicated; the second part of the double sound was little more than an echo, and was followed immediately by a well-marked blowing murmur, which ran up to the second sound. This post-systolic murmur was audible from the apex to the sternum and up to the lower border of the third rib, was lost over the aortic valves, and was scarcely, if at all, conducted beyond the apex towards the left. It disappeared when the patient held a deep inspiration, was intensified when he was lying on the left side, and materially diminished when on the right side. It was also diminished on resting, but did not entirely cease.

CASE 2.—A young man, aged twenty-one years, was examined by a medical man and passed for an office under a public body in June, 1996, when no murmur was detected. He was examined by another practitioner within the next few weeks, and a murmur found, and again with the same result six weeks later. He was advised to consult his own medical man, who at the first examination detected the murmur; but on seeing the patient a few days later when at rest failed to do so, and sent him to me. The patient was thin and pale, and was not conscious of palpitation or shortness of breath. He had never had rheumatism, and was able to lie on either side at night. When sitting the pulse was 126, small, regular, and compressible. When lying on the back a voluminous pulsation in the precordium was visible, with apparent displacement of the apex-beat downwards and outwards. This was, however, more apparent than real, as the nipple was three-quarters of an inch above its natural point. The apex was in the fifth interspace two and a half inches from the border of the sternum. On auscultation, when standing or sitting, a short, loud, blowing, systolic murmur could be heard at the apex and half an inch to the left of that point. This was conducted along the fifth rib to the centre of the sternum. The murmur was intensified during inspiration and was at a minimum at the end of expiration. On drawing a long breath as the end of inspiration was approached it became very high in pitch and resembled the sound caused by squeezing air through a hole in an india-rubber ball. When he held his breath at the end of a deep inspiration the heart became suddenly slower and two or three deliberate beats occurred which were unaccompanied by murmur. Fifteen minutes' rest in the recumbent position brought the heart down to 110, when the murmur could no longer be heard so long as he held his breath at the end of a deep inspiration, and the area over which the murmur was heard under other conditions was much reduced—that is to say, it was only to be detected over the immediate apex after rest.

CASE 3.—A woman, aged about twenty-eight years, was seen for headaches and nervous depression about four months

Hosted by Google

after her first confinement. The patient was somewhat anæmic, but otherwise looked well. She was able to move about briskly and was free from breathlessness. On examination of the heart the apex beat was found to be somewhat prominent, but in its normal position. The heart sounds were clear and rather accentuated, about eighty-five in the minute. A well-marked blowing murmur was heard in the fourth interspace about one inch from the left border of the sternum. It distinctly followed the first sound, and appeared to run up to the second sound, an interval occurring between the first sound and the murmur. The point of maximum intensity of this post-systolic bruit was at the place indicated, and it was well heard beside the sternum, but not at the base, and was scarcely audible at the extreme apex and not at all outside of it. At the end of a deep inspiration the murmur was absent. It disappeared after treatment by rest and arsenic.

CASE 4.—This patient, a married woman aged forty-one years, had been an invalid for some years. Fifteen years before she came under observation the ovaries were removed for tubal disease. She had not menstruated since the operation. She suffered much from palpitation and nervousness. The pulse was regular, jerky, 100, even when lying in bed. The area of the cardiac impulse was increased, and the whole of the precordial region heaved more or less with the systole. The extreme apex was behind the fifth rib three inches from the left border of the sternum. Notwithstanding the excessive impulse the cardiac dulness was slightly, if at all, increased. On auscultation at the extreme apex the sounds were very loud and "membranous," and a short blowing murmur accompanied the first sound. This was best marked towards the termination of the sound and increased in intensity as the sternum was approached, where it became musical. It was audible as high as the third interspace as a musical sound, but was merged in the second interspace in a soft blowing murmur (hæmic) At the end of a full breath it was much diminished, and it was greatly exaggerated when the patient lay on her right side. It was not audible to the left of the apex. At times when the patient was free from excitement the murmur was entirely absent.

CASE 5.—A boy, aged twelve years, with a nervous history, often had attacks of the nature of hysteria. He complained of giddiness and some shortness of breath on exertion. He had never had rheumatism. On examination of the heart there was a tumultuous heaving impulse. The apex was a little below the normal position; there was no thrill. A loud, short, systolic murmur could be heard to the left of the sternum. It was best marked about the fifth rib and was not audible at the immediate apex. There were no basic murmurs. The heart beat was 120, jerky and regular. The murmur became much more localised after resting, even though the number of heart beats was not reduced to any extent. On drawing a deep breath the murmur was absent at the end of inspiration. On lying on the right side the murmur was first intensified by the movement, but after a few minutes disappeared altogether.

CASE 6 —A man, aged twenty-nine years, had suffered from cough, night-sweats, and some emaciation for three or four months. He was highly nervous and somewhat short of breath. The right chest was flat beneath the clavicle, where the note was relatively dull. When standing, a loud, short, diastolic murmur could be heard to the right of the sternum. The point of maximum intensity was just above the right nipple, but it was audible from the clavicle to the fifth rib. The heart beat was jerky and nervous (120 in the minute), but after ten minutes' rest came down to 90 and the murmur disappeared. It also disappeared on the patient drawing a long breath and holding it. Over the same area a well-marked systolic cardio-respiratory murmur was heard during a quiet deep inspiration, but this was quite distinct from the sound already referred to. The pulse was small and rapid, but not suggestive of Corrigan's.

CASE 7.—Another case, closely resembling the above, was that of a man, aged thirty-eight years, who was admitted into the Royal Infirmary, Newcastle, in December, 1896, for cough and hæmoptysis. There was some retraction of the right lung and evidence of early phthisis. There was a short, whiffing, early diastolic murmur which terminated abruptly in the second sound. It was best heard between the apex and the sternum along the fifth interspace. It was loud on excitement, but disappeared on resting or on holding the breath.

CASE 8.—A man, aged twenty-nine years, of habitually nervous tendency, had complained for upwards of three years of a pain about the left nipple, which he ascribed to his heart. He had frequent attacks of palpitation with a feeling of intense apprehension of approaching danger, when he trembled all over. The pain was worse at night. The heart was rapid, 100 in a minute when standing. The left apex beat was in the nipple line between the fifth and sixth ribs. In the erect posture a loud, systolic, blowing murmur was heard at the apex, beyond which it was not conducted, being limited to within a narrow circle at this point. This murmur was intensified on drawing a long breath, and was increased in loudness as the inspiration reached its termination, but on holding a very long breath it disappeared. After lying down for a few minutes it was no longer audible.

A few points stand out prominently in connexion with these mimetic murmurs: firstly, they occur in highly neurotic people; secondly, they are frequently associated with violently acting ventricles independent of lung conditions; thirdly, they may be intimately connected with respiration and structural alterations in the lungs; fourthly, they are not limited to any cardiac area; fifthly, they may be systolic, post systolic, or early diastolic; and sixthly, they can be diagnosed by an appeal to certain tests, chiefly rest, position, and respiratory movements. (See table at end of first paper, THE LANCET, July 27th, 1895, p. 196).

Newcastle-on-Tyne.

A CASE OF PHTHISIS COMMUNICATED FROM HUSBAND TO WIFE.

BY WILLIAM MURRELL, M.D., F.R.C.P.,
LECTURER ON PHARMACOLOGY AT THE WESTMINSTER HOSPITAL.

A WOMAN, aged thirty-six years, was admitted into the Westminster Hospital suffering from phthisis. Both her father and mother were alive and well, and she had three sisters and one brother all grown up and in good health. There was no history of phthisis in her family on either side. Her husband was apparently healthy when she married him, but his father and one sister died from phthisis. After a time he developed a cough, spat blood, and ultimately died, it being stated on the certificate that the cause of death was phthisis. During the last seven months of his life he was too weak to go out, and his wife nursed him incessantly. They had only one small room, and the fire was kept burning day and night. He expectorated a great deal, and no directions were given her as to the use of antiseptics. Soon after his death she noticed that she had a bad cough, and when she came under observation it was found that she had cavernous breathing with whispering pectoriloquy at the right apex and dulness and crepitation at the left. She stated that she was no worse off in consequence of her husband's death, but that, on the contrary, her means had improved, as during her husband's illness she had to keep him.

Remarks.—This case is of no particular interest in itself, but it is so when taken in conjunction with similar cases recorded in THE LANCET of May 22nd, 1880, and a similar series of cases published by Dr. Reginald Thompson in THE LANCET of Nov. 6th of the same year, as marking the change of opinion respecting the contagiousness of phthisis which has taken place since that time. Sixteen years ago such cases were regarded with suspicion and their publication excited hostile criticism; now they are so common that they excite but little comment. Dr. Hermann Weber[1] gave details of thirty-nine wives who became infected from marrying phthisical husbands, and in several cases the husband infected more than one wife. The reason the husband infects the wife more frequently than the wife the husband is explained by the fact that when the husband is ill the wife nurses him, but when the wife is ill the husband from the increased demands on his resources has to pay closer attention to business and is less at home than usual. In connexion with the subject of the contagiousness of phthisis it is difficult to avoid reference to the risk which is run by healthy people on long sea voyages if compelled to occupy the same cabin with patients suffering from advanced phthisis. The sleeping cars which convey large numbers of phthisical patients to the Riviera and other popular health resorts at certain periods of the year are not above suspicion, and much greater care should be taken in having them aired and disinfected than is at present the case.

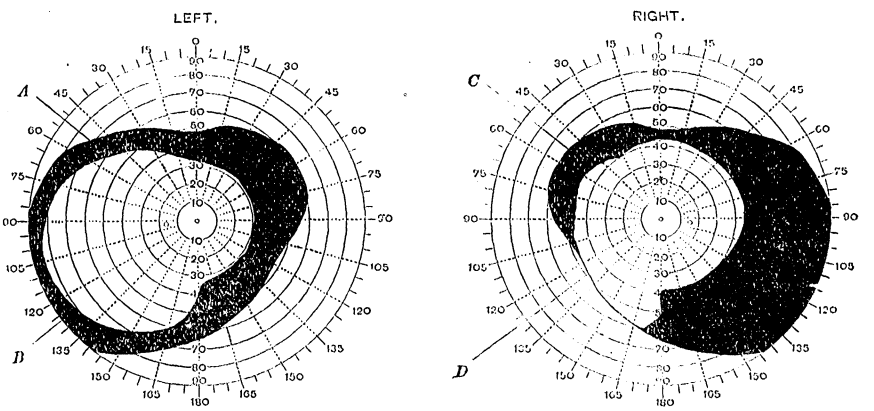
ILLUSTRATIVE CASES OF APHASIA.

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.



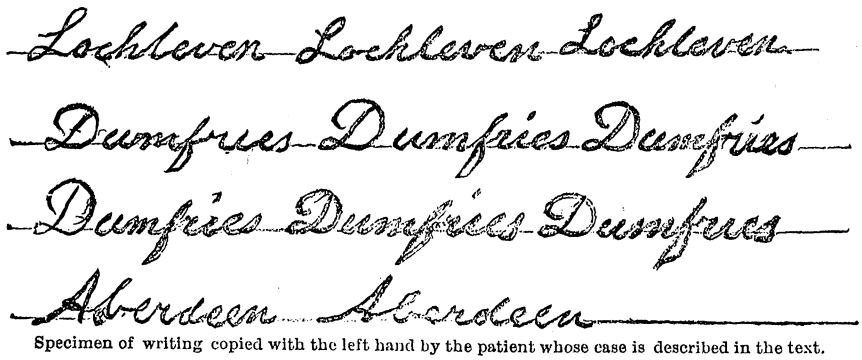
(*Continued from* p. 953)

CASE 4. *Paralysis of the right hand and arm; aphasia; very marked word-blindness presenting the peculiarity that the patient could read many words (combinations of letters) while he was absolutely unable to recognise the individual letters of which they were composed, with some impairment of the motor side of the speech mechanism; partial right-sided homonymous hemianopsia, with some peripheral constriction of the sound half of each field.*—This case was brought before the Edinburgh Medico-Chirurgical Society, and published in the *Edinburgh Medical Journal*, September, 1887, p. 241. It is of great importance, for, so far as I know, attention had not been previously directed to the interesting fact that some word-blind patients can read words (combinations of letters), and yet are unable to read the individual letters of which those words are composed. It is curious that the case seems to have been almost entirely overlooked, not only abroad, but in this country. I re-publish it exactly as it was originally printed, and without any addition to the comments which I then made, further than to say that some similar cases have since been recorded and that the same explanation of the facts which I originally advanced has also been suggested by other and independent observers. The following is the original record.

"The point of greatest interest in this well-marked case of word-blindness is the fact that the patient, who was absolutely ignorant of the individual letters and did not even recognise them when they were named to him, was nevertheless able to read many words—i.e., letters when taken in combination. I am not aware that such a condition has been previously described. It is usually supposed that the highest degree of word-blindness is manifested by inability to read individual letters rather than individual words—that, in short, individual letters, which are generally considered to be the most elementary parts (least highly specialised) of written speech, as they undoubtedly are the first to be acquired, are the last to be lost and destroyed. It might therefore at first sight be argued that the fact that a word-blind patient who was utterly ignorant of the individual letters, as letters, was nevertheless able to read combinations of letters or words was opposed to the great doctrines of evolution and dissolution which Herbert Spencer, Hughlings Jackson, and others have so satisfactorily applied to the elucidation of the pathology of the nervous system, and which so greatly aid the intelligent comprehension of the derangements of the functions of the brain. When, however, the matter is looked at more closely this apparent exception will, I think, be found to conform to the general rule, for after the preliminary difficulties of learning to read have been overcome, and the act of reading has become facile and has been frequently repeated, the individual letters are, by some persons at all events, ignored, and it is the combination of letters—syllables and individual words—to which attention is chiefly directed. In short, it may be supposed that in some persons the syllable and individual word become after a time less highly specialised (i.e., more elementary) parts of written speech (when read) than the individual letters. If this be so we should expect the form of word blindness which I am now describing to be more frequent in well educated and intelligent people, to whom the act of reading has, as it were, become automatic, than in uneducated persons and those who before their illness could only read with difficulty and by spelling out (by the help of individual letters) the separate syllables and words. The notes of the case are as follows.

"A very intelligent man, aged sixty years, who had for many years occupied a responsible position as clerk of works, was sent to me on March 9th, 1887, by the late Dr. T. G. Balfour, suffering from paralysis of the right arm and aphasia. He stated that he had enjoyed excellent health until April 15th, 1886, when he lost the power of moving the thumb and forefinger of the right hand. The paralysis was only slight, and passed off in the course of a few days. Speech was not affected on that occasion. He remained well until Oct. 7th, 1886, when he had a second attack. On this occasion all the fingers of the right hand were powerless, but the movements of the elbow and shoulder were not affected, nor was speech implicated. He slowly and gradually recovered from this, as he did from the first attack, and continued to follow his employment as clerk of works until Dec. 22nd, 1886, when the present attack came on. On the morning of Dec 22nd he felt sick when he got out of bed; loss of power in the right hand and arm and inability to speak then developed, and were complete in the course of a few hours. Neither on this nor on either of the two previous occasions was the onset of the paralysis attended with coma. At first the loss of power was almost complete in the upper arm and forearm as well as in the hand, but in the course of a few weeks he began to move the arm at the shoulder and elbow. There has been no perceptible improvement in the paralysis of the hand nor in the power of speaking. The leg and face were in no way affected. On March 9th, 1887, when the patient first came under my observation, there was absolute inability to move the fingers and thumb of the right hand; the patient could pronate, but was unable to supinate, flex, or extend the hand on the wrist; all the movements of the elbow and shoulder could be performed. The muscles acting upon the elbow and shoulder were, however, still markedly paralysed, the movements which resulted from their contraction being very feeble and unsteady. The fingers and thumb of the right hand were rigid and bent into the palm. The right hand and forearm were swollen, and the skin felt sodden and was more moist than that on the opposite side. No distinct increase of the tendon reactions, as compared with those in the left arm and forearm, could be detected. There was absolutely no loss of power in the right leg, and the reflexes, both superficial and deep, seemed quite natural and equal in both lower extremities. There was no perceptible right-sided facial paralysis, but the patient, who had lost all his upper teeth, seemed to have some difficulty (probably not paralytic) in moving the upper lip on both sides. The skin sensibility was markedly impaired in the right forearm and hand, more especially over the fingers and on the outer (extensor) aspect of the forearm.

FIG. 8.



Perimeter chart of the fields of vision for white in Case 4, showing partial right-sided lateral homonymous hemianopsia, peripheral constriction of the whole of the left half of the field in the left eye (the parts to which the letters A and B point), and constriction of the upper part of the left half of the field in the right eye (the part to which the letter C points).

Hosted by Google

In the upper arm there also appeared to be some loss of tactile sensibility, but there was apparently no anæsthesia in the right leg. The exact testing of the skin sensibility was, however, difficult because of the inability which the patient had in expressing himself. The visual acuity seemed equal and normal in the two eyes. The pupils were equal and contracted both to light and to accommodation. No abnormal ophthalmoscopic appearances were observed. Perimeter measurements, made on March 11th and 12th, showed partial right homonymous hemianopsia, with some concentric limitation of the field in the left (seeing) half of each field (see Fig. 8). The hemianopsia was probably more marked than is shown in the figure, for the patient, who was very definite and certain in his answers when the left side of the field was being taken, was uncertain and hesitating when the right side of the field was being examined. The parts of the fields coloured black in the charts were absolutely lost. Hearing, taste, and smell, so far as they could be tested, owing to the aphasic condition of the patient, seemed equal and natural on the two sides. The heart seemed normal. The urine was very pale, and its specific gravity 1010; it was acid, not too copious, and contained no albumin. A high degree of aphasia was present. On analysis it was found to consist of very marked word-blindness, with apparently some degree of motor aphasia (amnesia) in addition. When the patient first came under observation I was doubtful if there were not some 'word-deafness' or lack of comprehensive (intellectual) power. When asked, for instance, on March 14th, whether he was a hundred years old he at once expressed emphatic dissent both by gesture, expression, and verbally, saying, 'Oh, no.' But when asked immediately afterwards if he was thirty he hesitated for some time and finally answered 'Yes.' Immediately after this he at once and emphatically said, in answer to questions, he was not forty and not fifty. This defect, if any, of intelligence in comprehending spoken language was, however, only temporary. Since March 21st I have not observed any mistakes of this kind. A more careful analysis of the speech condition at the time when the patient first came under observation showed the following facts.

FIG. 9.

Specimen of writing copied with the left hand by the patient whose case is described in the text.

"*Motor functions of speech; motor aphemia.*—The patient had lost the power of spontaneously speaking in sentences. He was also unable to name most common objects (such as a knife, pen, key, or pencil) which were shown to him, but he always knew what they were, and was at once able to repeat their names when they were mentioned in his hearing. He was able to make a few intelligent replies to questions in single words, and to use the words 'Yes,' 'No,' and 'Oh, no,' in an intelligent and propositional sense.

"*Agraphia.*—He had lost the power of spontaneously writing in sentences. He had also lost the power of writing from dictation. He was unable to write any letter of the alphabet when told to do so. He could, however, copy both printed and written characters with his left (non-paralysed) hand quite as well as most right-handed persons (see Fig. 9). He could also draw with his left hand at least as well as most right-handed persons (see Figs. 10 and 11). He knew the different parts of the house which he drew; and, although he could not himself name them, he at once pointed correctly to the different parts when they were named to him.

"*Sensory functions of speech.*—With the qualification mentioned above there seems to be no word-deafness. There is, however, very marked word-blindness. The patient is, as has been already mentioned, well acquainted with

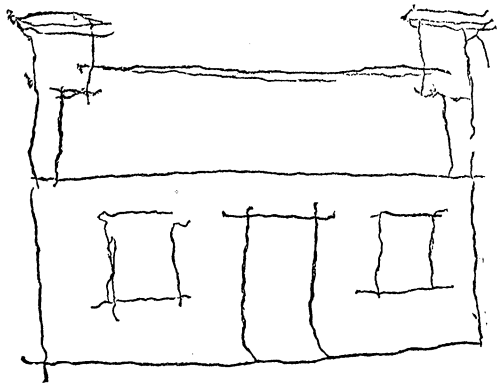


FIG. 10.

Facsimile of drawing of a man's head made with the left hand by the patient whose case is described in the text.

ordinary objects (such as a knife, pen, pencil, &c.), which are shown to him, although he cannot name them spontaneously. He also at once recognises pictures and portraits (the Queen, Prince of Wales, Edinburgh Castle, the Scott Monument, &c.). He is, however, unable to recognise a single letter of the alphabet; he can neither spontaneously name the letter when it is shown to him, nor can he, when the names of different letters are repeated aloud to him, indicate when the particular letter which he is asked to recognise is named. He is also unable to recognise figures, either spontaneously or when they are named to him. On March 11th he was asked to name the letters and figures on a calendar for the month which was standing on my table. The result was as seen in Fig. 12. The letter O is the only one which was correctly named; the T (in THR.)

FIG. 11.

Drawing of a house made with the left hand by the patient whose case is described in the text. Drawing reduced from 4 to 2½ inches.

was correctly named, but in SAT. was named 'N'; the N in both SUN. and MON. was named 'T.' Numbers were on this occasion named as letters; 2 was called 'R,' 9 'N,'

Hosted by Google

and so on. At the same visit he copied the letters TUE correctly, but named them, after he had copied them, 'STH.' He also wrote from dictation, on the same occasion, 'T' for A, 'S' for B, 'R' for C, and when told to write D, E, F, said 'I cannot' or 'I do not know.' Efforts of this kind, and, indeed, any sustained attempt to speak, read, &c., were attended with marked flushing of the face, perspiration of the head, and appearance of great effort. The patient was advised to diligently practise his writing, and to try and read and learn the alphabet.

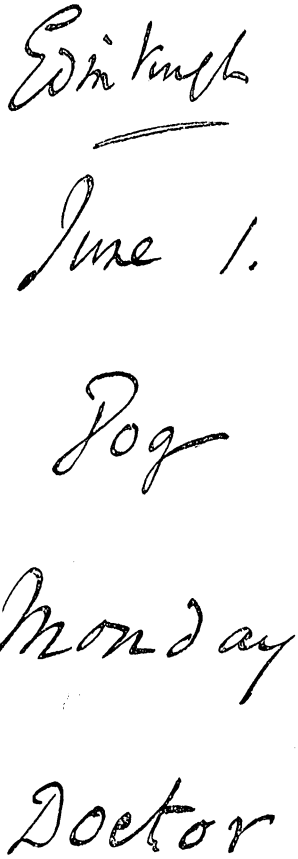
Copy of a portion of a calendar for March, 1887, showing the mistakes made by the patient (Case 4). The letters in the word March were read as "Netos," &c. (Same size.)

"*Subsequent progress of the case.*—His general condition and loss of speech slowly and gradually improved. Motor power was, to a considerable extent, regained in the muscles of the upper arm and forearm; the muscles acting upon the wrist and fingers have, however, remained until the present date, June 20th, absolutely paralysed. The swelling and moisture of the paralysed hand have almost disappeared. On May 18th spontaneous speaking in sentences was still lost; the patient could now name many more objects than when he first came under observation; and in replying to questions a few more words were made use of. He was still quite unable to write spontaneously or from dictation. He could not even write his own name, though he made, on this and several other previous occasions, more or less satisfactory attempts to do so. He was still, as a rule, unable to write any letter of the alphabet when told to do so. On June 1st, when he was shown to the Medico-Chirurgical Society of Edinburgh, he could not write or recognise the letters 'o,' 'a,' or 's,' which I wrote on the blackboard, nor did he know these letters when they were named to him. He had recognised these letters on a previous occasion; and I had more than once found that he could write and recognise some letters which, perhaps, at the next visit, or if he was tired or agitated, he seemed to be quite unacquainted with. He was now able to write some of the individual letters, such as 'a,' 'o,' or 's' when told to do so; and if he made a correct start, and wrote the letter 'a' from dictation, he was sometimes able to go on and to write many letters correctly and in their right order. On one occasion he got up to the letter 'p' in this way (see Fig. 13). He was, however, quite unable to read any letter after he had written it. He could not point out the letters 'a,' 'c,' 'o,' for instance, in the line of letters which he had written; and even when the letter to which his attention was being directed was correctly named to him he did not recognise that it had been named. In this respect (the power of spontaneously writing some letters which he was quite unable to read after he had written them) the case seems to resemble in an early stage the case of word-blindness described by Westphal, 'in which the patient, at first unable to read his own writing, acquired the power of deciphering it by passing the tip of his index finger over each letter as if he were writing the word a second time.'[1]

"Soon after the patient first came under my observation his wife, who always accompanied him when he came to see me, stated that he was able to read and make out some things which interested him in the newspapers. I paid very little attention to this statement, for it is well known that aphasic patients who are utterly unable to read a single word not unfrequently occupy themselves with a book, newspaper, or a paper, and appear to their friends to be intelligently interested. Knowing, then, that this patient was unable to read a single letter of the alphabet, I paid no attention to this statement. When, however, his wife stated on a subsequent occasion that he had, when walking in the cemetery, read to her the names (with which, be it observed, he had not been previously acquainted) on some of the tombstones quite correctly, and also that he had, on another occasion, turned up and pointed out in a guide-book the name of a

FIG. 13.



Facsimile of alphabet written by the patient (Case 4) on May 21st. The alphabet was correctly written up to the letter P. The patient was unable to read any of the letters after he had written them, and did not even recognise them when named to him.

[1] Quoted by Ross, Aphasia, p. 75.

Hosted by Google

landlord about whose property they were talking, my attention was aroused, and I found on investigation that the patient could read many words the individual letters of which he was totally ignorant of, even when they were named to him. Thus, on June 1st he read correctly the words which I had written on a piece of paper (see Fig. 14); also the

FIG. 14.

Facsimile copy of words read by the patient (Case 4) on June 1st. He was unable to recognise any of the individual letters contained in these words, even when they were named to him.

words 'house' and 'cat' written in the same way; 'book,' he said, was 'boot,' and 'something' he read as 'someone'; the words 'hand,' 'right,' 'left' he was unable to read. He was totally ignorant of the individual letters composing the words which he was able to read, and did not even know them when they were named to him. Thus he was asked with regard to the first letter in the word doctor, which he had read correctly, Is it 'a'? Is it 'b'? Is it 'c'? Is it 'd'? and he failed to give any sign that he connected the sound 'd' with the written symbol. And so on with all the other letters. His knowledge of figures was now better than it used to be, but still very imperfect.

"At the end of June, 1887, the patient's condition was essentially unchanged. I have had no opportunity of examining him since that time."

Corrigenda.—Case 3, page 950, seventeenth line from the foot, instead of "I am consequently" read "I was consequently."—Page 951, second column, seventh line from the foot, instead of "read it" read "tell me what he had written."

(To be continued.)

MEDICAL MAYORS.—Mr. William F. Prichard Bassett, M.D. Edin., M.R.C.S. Eng., has been re-elected mayor for the city of Bathurst, New South Wales.—Mr. A. Clarke Robinson, M.D. R.U.I., L.R.C.S. Edin., has been elected mayor of Jerilderie, New South Wales.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF MULTIPLE DUODENAL ULCER.

BY F. J. DE COVERLY VEALE, M.B., CH.B. VICT.,
LATE ASSISTANT MEDICAL OFFICER, COUNTY ASYLUM, LANCASTER.

THE following is a brief account of a case I had under my care in the early part of 1896.

A man, aged sixty-eight years, of temperate habits, was admitted to the County Asylum, Lancaster, on Dec. 19th, 1895. Mentally he was advanced in senile dementia, wet and dirty in his habits, and he required a single room at night. He rapidly became feebler, and was transferred to hospital, but not put to bed. He at no time made any complaint of physical trouble, though his mental condition may account for this. He refused his food from about Feb. 10th, 1896, and had to be fed with a spoon. He was taking only soft foods, and was losing weight. On the 17th, about one and a half hours after breakfast, he vomited. This was thought to have been due to constipation, and a dose of salts was ordered. The vomited matter was said to be "bilious," but I did not see it. No further change was noticed until March 3rd. On this date the night attendant found that he had been vomiting "coffee-grounds." This was at 6 A.M. He was put to bed in hospital, and I was subsequently called to see him. He was very feeble and *in extremis* Nothing could be made out by examination. I inspected the vomited matter and suspected gastric ulcer, and treated him accordingly. During the day he became still feebler. He had two attacks of hæmatemesis during the night. He was also reported to have had two convulsive seizures, but not at the same time as the vomiting. He died at 5.15 A.M. on March 4th.

Necropsy.—In the first part of the duodenum there were four ulcers, all within two inches of the pyloric valve. The largest ulcer was of the size of a split pea, its edges showed considerable induration, and it involved all the coats of the bowel, the peritoneal covering being much thickened locally. The second ulcer was similar in size, but its edges were less indurated and it was more superficial. The remaining two ulcers were quite small, and merely involved the mucous membrane and submucosa. All these ulcers were deeply coloured by the deposition in them of disorganised blood products. The œsophagus and stomach showed similar deposits on their walls, whilst the fæces in both small and large bowels were almost black in colour from the same cause.

For the notes of the necropsy I am indebted to Dr. Goodliffe.

Lancaster.

NOTE ON A CASE OF SUPPOSED POISONING BY PENNYROYAL.

BY W. T. ALLEN, M.B., B.CH. R.U.I.,
RESIDENT MEDICAL OFFICER, PARISH INFIRMARY, LIVERPOOL.

A WOMAN, aged twenty-three years, was admitted to the parish infirmary, Liverpool, on March 15th, in an almost collapsed condition, suffering from symptoms of acute gastritis. She stated that vomiting began four days previously after she had taken a tab'espoonful of pennyroyal. She had taken this drug to bring on menstruation, which had been in abeyance for six months. The excessive vomiting continued despite the usual remedies, but ultimately ceased under the influence of morphia and rectal alimentation. The patient, however, gradually sank, and died on March 19th. She had been an inmate of the infirmary for a week at the beginning of the month, and was then suffering from slight anæmia and dyspepsia, but had not vomited during that period.

A post-mortem examination was made at the direction of the coroner, and I found the stomach extremely congested, especially towards the cardiac end, the small intestines also showing thickening of their coat and intense congestion,

Hosted by Google

most marked in the lower part of the ileum. The large intestines were also congested even down to the rectum, but not to the same degree as the stomach or ileum. The uterus was normal in size, and there was nothing noticeable in the other organs except some congestion of the brain. At the inquest evidence corroborative of the woman's statement was given; but as the druggist who had sold the pennyroyal said that in thirty years' experience he had never heard of a case of poisoning by this drug, the jury returned a verdict that "death was due to gastro-enteritis set up by some irritant poison" but did not decide what the poison was. It is in deference to their verdict that I have put the word "supposed" in the heading to this note. On looking up the literature of the subject I have only been able to find one case of poisoning by pennyroyal, which is recorded in Dixon Mann's "Forensic Medicine." In that case a pregnant woman who was seen immediately after taking a one-drachm dose of the drug had vomiting, delirium, and opisthotonos, but subsequently recovered.

Liverpool.

A NOTE ON A FATALITY OCCURRING UNDER ANÆSTHETICS.

BY HUGHES REID DAVIES, M.R.C.S. ENG., L.R.C.P. LOND.

A CASE of left pleural effusion of many years' standing came under my care in 1889. From that date up to about the early part of 1896, except for occasional attacks of general debility, dyspnœa, and bronchitis, the patient managed to tide over year after year and follow his daily avocations without warranting surgical interference. However, a severe attack of broncho-pneumonia converted the fairly quiescent left thorax into an empyema. Bronchiectasis was also diagnosed; and, finally, when the pus found its way into the dilated tubes, the fœtor of the expectoration rendered life a burden, not only to himself, but to those around him. The misery of his life induced him to accept the offer of surgical aid. Every precaution to ensure success was taken. A well-known and skilful hospital surgeon was present, a physician, myself, and another surgeon. Chloroform was administered, the patient being gently lowered into as recumbent a position as his breathing allowed. The anæsthetic was taken well, the radial pulse being carefully felt by me, and the temporal by the anæsthetist. Neither pulse nor respiration were such as to warrant alarm. Stertor commenced, and the patient was announced by the anæsthetist as "ready." Then came our error of judgment, an error which THE LANCET, in the article entitled "The Records of Fatalities under Anæsthetics," published last week, shows to be common to others. Dorsal decubitus was exchanged for the right side position. In an instant a marked change occurred; a gurgling, bubbling effort of respiration was followed by complete cyanosis and cessation of respiration and heart's action. With the utmost rapidity the patient was turned upon his back, untouched by the surgeon's scalpel, and artificial respiration and subcutaneous injections of ether and brandy at once commenced, but though persisted in for some considerable time they were useless. Effect and cause seem plain. Up to the moment of turning the patient for operation anæsthesia was going fairly well. Simultaneously with the change from dorsal decubitus to right side position the empyema emptied itself rapidly into and through the dilated bronchi, filling the trachea, right bronchus, and even the mouth, as the "bubbling" in my case and the pouring of fœtid pus from the mouth in Mr. Scott's case testified. The change to the original dorsal position, artificial respiration, &c., quick as they were, were futile. The sound lung was choked, the embarrassed heart-action impeded beyond recovery, the respiratory centres responded no longer, and death from asphyxia resulted.

Surely, no one will say that the anæsthetic was to blame? and yet the case must be quoted as "death under anæsthetics." Had we but tried, before anæsthesia dulled the respiratory centres, the position required for operation, reflex coughing would at once have warned the patient and us of the impossibility of that position; or had we before anæsthesia withdrawn with a large trocar and cannula all the fluid possible from the pleural cavity we might, perhaps, have been spared our painful and much-regretted experience.

WESTMINSTER HOSPITAL.

A CASE OF NEGLECTED TYPHOID FEVER; PERFORATION AND EXTRAVASATION OF FÆCES INTO THE SAC OF A LEFT INGUINAL HERNIA; DEATH AFTER RAPID EMACIATION.

(Under the care of Mr. W. G. SPENCER.)

THE following case is noteworthy on account of the exceeding difficulty in diagnosis and the great rarity of an intestinal ulceration due to typhoid fever perforating into a hernial sac. Extensive adhesions must have localised the peritoneal inflammation resulting from the perforation, or the patient could not have survived so long as a month after the perforation occurred, for perforation took place probably on Jan. 21st. The rapid wasting is remarkable considering that the site of the fæcal fistula was so close to the ileo-cæcal valve.

A man, aged thirty-eight years, last went to work on Dec. 22nd, 1896. He then stayed at home, complaining of pains all over him, and had shivering, sweating, and diarrhœa. He did not take to his bed, however, until Jan. 21st, 1897—i.e., a little more than four weeks after leaving work; he was then obliged to do so on account of great pain in the lower part of the abdomen. During three or four days he vomited several times yellow or brown matter; he wandered at night, and on two or three occasions had difficulty in passing urine. He had had a rupture on the left side for nine years, which used to come down when he was at work and go back on lying down; but after the attack of pain and vomiting it could not be returned, but, on the other hand, became more tense and caused much pain. He was admitted to hospital on Jan. 31st—i.e., about six weeks after leaving work—and his medical attendant is reported to have sent word that he was suffering from phthisis after influenza. A large swelling filled the left half of the scrotum and extended to the inguinal region, the skin over it being dusky red and œdematous. The swelling was tympanitic to percussion, yielded evident fluctuation, and was opaque to light, and a firm mass filled the inguinal ring and gave an impulse on coughing. The penis, the right side of the scrotum, and the perineum were normal. The temperature was 102·6° F. and the pulse was 130. The bowels were opened soon after admission. No vomiting had taken place for several days, nor did it occur before the operation. Mr. Spencer formed the diagnosis of a ruptured hernia and made an incision the whole length of the scrotum. Pus, fæces, and flatus escaped, and a mass of sloughing omentum was cut away without disturbing the adhesions shutting off the abdominal cavity. There was no bowel in the sac, but fæces welled up under the omental stump from a cavity just inside the ring. The sloughing hernial sac was treated antiseptically and frequently irrigated, and the sloughs, which included the testicle and cord, were later cut away piecemeal, so that before the patient's death a clean granulating surface had formed. For a few days the patient seemed to improve, but he soon rapidly wasted and was reduced to a skeleton before death. This wasting occurred in spite of the patient taking abundant food by the mouth and extras such as cream, alcohol, and cod-liver oil, which was also rubbed in. He was intolerant of enemata. The patient had regular motions per anum, and there were frequent discharges of fæces by the wound, sometimes yellow and sometimes green. Throughout the case there was an absence of odour in the fæces; the ward sister made the remark that the stools had the colour but not the consistency of typhoid stools. The abdomen was not palpated much for fear of breaking down adhesions; it was, if anything, rather retracted, always soft, and not tender, except one day when

Hosted by Google

there was some retention of pus. The patient's only complaint was of griping abdominal pains. The tongue throughout was moist and clean. The temperature fell after the operation and was subnormal for a week before death; the pulse was always from 100 to 120 or more. The patient died seventeen days after admission, about two months after leaving work.

Necropsy.—At the post-mortem examination, which was performed by Dr. Hebb, the omentum was found stretching from the colon to the left inguinal ring, thus forming an apron covering the lower half of the abdomen. Beneath it, in the pelvis, the lower portion of the small intestines had become matted together, mixed up with pus and fæces, with the gut so rotten that it tore in all directions when drawn upon. The oldest and largest perforation was situated just above the ileo-cæcal valve, but for four feet above the valve all the Peyer's patches were ulcerated down to the peritoneal coat or had actually perforated. The mesenteric glands were enlarged and the spleen was soft. Indeed, there is no doubt that the patient's illness was the result of typhoid fever.

SUSSEX COUNTY HOSPITAL.

A CASE OF TETANUS FOLLOWING PUNCTURED WOUND OF THE HAND TREATED BY BINIODIDE OF MERCURY BATH AND ANTITOXIN; RECOVERY.

(Under the care of Mr. N. P. BLAKER.)

THE interest in this case chiefly lies in the fact that the patient was treated by biniodide of mercury baths locally. When mixed treatment, however, is tried it is difficult to learn much for future guidance, and here the patient was given chloral and other drugs, besides having anti-tetanic serum injected. How far the use of the serum was of benefit we cannot judge; there is one thing established about its administration, and that is that the immunity which it confers is greatly superior to its curative qualities, and when the disease is once developed far greater quantities must be used than are necessary to induce immunity. "In summing up it seems to the author[1] that the serum treatment has not actually changed the prognosis in acute and serious cases. In the milder cases it seems to lessen the spasms, the pain, and the distress, and, fortunately, it has reduced the mortality, but to what extent cannot be told until we are certain that all cases are published." Kanthack[2] has pointed out that the severity of tetanus and the seriousness of its prognosis depend, among other things, upon the rapidity of the onset, the acuteness of the case, and the period of incubation—i.e., the shorter the incubation the more serious the outlook. For the notes of this case we are indebted to Mr. A. H. Buck, house surgeon.

A boy, aged fifteen years, was admitted into the Sussex County Hospital on June 12th, 1896, under the care of Mr. Blaker, on account of secondary hæmorrhage from a punctured wound of the palm of the hand. The wound was caused by a fall on broken glass in the road on June 8th, and was followed by free hæmorrhage, which was stopped by pressure. Hæmorrhage recurred on the 11th. At the time of admission there was in the middle of the palm of the left hand over the superficial palmar arch a clean deep cut half an inch long. There were then neither signs of inflammation about the wound nor yet signs of healing. No injury to tendons or nerves was discovered, and after washing with carbolic lotion a pad of cyanide gauze was applied. On the 13th the temperature was 100° F., and the hæmorrhage again recurred and was stopped by pressure. The temperature did not rise again above 99°, but on dressing the wound two days later there was a little pus present, after which it was dressed daily. On the afternoon of the 20th the patient complained of a stiff neck, and on examining him the house surgeon found he could not open his mouth or sit up in bed on account of rigidity in the muscles of the back. He was moved at once to a separate ward, which was darkened and kept quite quiet, and under chloroform the wound was opened up freely with a pair of dressing forceps. The hand and forearm were then put into a bath of biniodide of mercury of the strength of 1 in 500. Internally fifteen grains of chloral hydrate were given every four hours. On the 21st, at 8 A.M., the patient had a severe attack of opisthotonos and was sick. Swallowing became so difficult that nasal feeding was resorted to. The chloral was discontinued, and ten minims of tincture of opium were administered every four hours. Some improvement took place during the day, but at any stimulus, such as noise or draught, the spasms recurred. Twitchings of the face were also troublesome. Towards night the patient could swallow more easily and was fed with a spoon, the teeth not admitting of separation for more than a quarter of an inch. In the evening the temperature was 101° F., the pulse was 120, and the respirations were 20. On the afternoon of June 20th a telegram was sent to the British Institute of Preventive Medicine for tetanus antitoxin, but late at night an answer was received saying that there was none in the institution. On the 21st (Sunday) telegrams were despatched to two firms of druggists, both of whom sent off antitoxin on the 22nd (Monday) as soon as their premises were open. The use of antitoxin was, however, delayed for nearly forty-eight hours, at which time, as it happened, the symptoms were already showing signs of abating. On the 22nd the patient was better, after a fairly good night. The rigidity of the muscles of the back was well marked and there were also trismus and risus sardonicus. There were no acute spasms. There was slight nausea, but no vomiting. The patient was quieter and in less pain. The left hand had been in a bath of biniodide continuously since the symptoms were first noticed, and the palm and dorsum presented large blebs. Considerable absorption must have been taking place. At 12 midday a dose of antitoxin was injected subcutaneously in accordance with directions sent with the bottle. At the time of injection the temperature was 100°, and during the following twenty-four hours it did not rise above 100·8°, nor did the pulse exceed 122. On the 23rd the spasms were few in number, but the back was still very rigid. The trismus and risus sardonicus were well marked. The patient could swallow better. A second dose of antitoxin was administered at 11 A.M; the temperature rose to 101·4° twelve hours later; otherwise it remained between 100° and 101°. He slept fairly and had taken food well—three pints of milk, three ounces of brandy, and six eggs during the last twenty-four hours. The strength of the bath of biniodide was now changed to 1 in 2000. During the afternoon the opisthotonos and twitchings were more severe. The strength of the bath was again changed in the evening to 1 in 500. On the 24th the patient was better as to pain and spasms. The bowels were opened after an enema. Slight salivation appeared towards the evening, and the biniodide bath was changed for boracic fomentations. Some of the blebs had broken and others were still of large size. On the 26th there were considerable pain and twitching of the face and muscles of the back. The hand was put in the biniodide bath (1 in 500) for half an hour. The temperature remained at from 100·6 to 101·6°. After this the symptoms slowly and gradually improved and the bath was given for from one to two hours a day. On the 30th the tincture of opium was diminished to four minims every four hours, and on July 9th to three minims, and on the 12th to two minims, being discontinued altogether on the 15th. On the 18th the bath was discontinued, and the patient could then turn about easily in bed and sit up. On August 1st the curve in the upper dorsal region was somewhat exaggerated, and there was still slight rigidity of the muscles of the back. The intercostals did not act well and the breathing was mainly diaphragmatic; the patient was, however, looking very much better and was getting out of doors. The trismus had disappeared. On the 15th the above condition had very much improved, and the patient left the hospital practically well eight weeks after the appearance of the first symptoms.

Remarks by Mr. BUCK.—The following points seem to me to be of special interest in connexion with the above case, and have induced me to place it on record:—1. There is, so far as I know, no recorded case of the treatment by a bath of biniodide of mercury having been tried. An acute case of tetanus successfully treated by subcutaneous injections of corrosive sublimate has been reported by Celli.[3] Biniodide was used in preference to sublimate on account of its non-precipitation with albumin, which rendered its absorption more easy and certain and ensured the cessation of such absorption as soon as desirable; whilst the sublimate forms a store of more insoluble albuminate of mercury

Hosted by Google

in and about the wound, which might continue to enter the system after symptoms of mercurialism had appeared. The strength of the solution used (1 in 500) was such as to produce blebs of considerable size in thirty-six hours, but no signs of salivation or soreness of the gums were observed for four days. These symptoms speedily disappeared with the cessation of the bath for thirty-six hours. After this the hand was immersed for from one to two hours daily for three weeks, and there were no further signs of mercurialism. 2. The administration of the bath was quickly followed after the first twenty hours by great amelioration of the symptoms, and if afterwards these at any time became more severe the use of the bath was noticeably followed by relief. The fact that the absorption of the biniodide took place by the same paths as the absorption of the poison may have had something to do with this, and in cases where the infected wound is in such a part of the body that it cannot be treated by a continuous bath subcutaneous injections of a solution of biniodide might be tried in the neighbourhood of the wound or even into the wound itself. 3. Owing to the delay in obtaining the antitoxin the first injection did not take place till forty-eight hours after the appearance of the symptoms, by which time the boy had considerably improved. There was no apparent reaction after either injection. 4 The period of incubation, twelve days, was of average duration and might precede an acute or chronic attack; the symptoms were, however, alarming within twelve hours of their onset. It was remarkable how little inflammation was present about the wound during the first twelve days. The case was throughout treated under the supervision of Mr. Blaker, and I am indebted to his kindness for permitting me to publish it.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Actinomycosis of the Pleura and Chest Wall.—Cyst of Omentum.—Concretions of the Rectum.—Traumatic Hydrocephalus.—Infective Venereal Tumours in Dogs.—Tuberculous Peritonitis associated with an Inguinal Pouch of the Peritoneum.—Healthy Œsophagus Ruptured by Vomiting.

A MEETING of this society was held on April 6th, Mr. EVE, Vice-President, being in the chair.

Dr. SAMUEL WEST showed a case of Actinomycosis of the Pleura and Chest Wall. The specimen was removed from a boy, aged six years, who was admitted as a case of empyema. He had been ill for nine weeks with pain in the chest and shortness of breath, and a few days before admission a fluctuating swelling had formed in the fifth left intercostal space. This was incised, and a small quantity of thick pus escaped, which was examined by Dr. Kanthack and found to contain actinomycotic filaments. Two weeks later another swelling formed in the chest wall, which was also incised; it did not appear to communicate with the pleural cavity. The sinuses continued to discharge, and two months later iodide of potassium was given in increasing doses till thirty grains per diem was reached. There was at once a marked improvement, and it seemed that the child might recover, but he died unexpectedly during the administration of chloroform for the extraction of a tooth, although he had previously taken it well on two occasions. At the necropsy the left lung was found completely collapsed, and the pleural cavity was filled with cheesy material and collections of pus. The chest wall was much thickened, the ribs, which were unaffected, being embedded in dense fibrous tissue in which a very few actinomycotic groups could be found after careful searching. No deposits were found in the lungs. The case was remarkable on account of the age of the patient, of the escape of the lung, and of the striking improvement under the administration of iodide of potassium.—Dr. EDMUND GREEN mentioned a case of disseminated actinomycosis in a boy, fourteen years of age, who had first a swelling across the lower part of the abdomen, which was opened, and later another over the ninth costal cartilage, and a third in the left inguinal region. The fungus was found in the pus, and iodide of potassium administered with temporary success, but now the patient was going down hill.—Mr. CECIL BEADLES mentioned a case of actinomycosis of the mamma, in which an abscess was opened, and was found to communicate with the interior of the thorax by a sinus which could be tracked down the thorax to the region of the liver.—Dr. A. F. VOELCKER had performed a post-mortem examination on a case which had been under treatment for some time for actinomycosis of the skin. The lower lobe of the lung was firmly adherent to the chest wall by dense fibrous tissue as in Dr. West's case, and in the liver there was a cicatrised patch of actinomycosis. There was also double psoas abscess, the pus containing actinomycetes, and there was amyloid disease of the liver and other organs. There had been temporary improvement under iodide of potassium.—Mr. EVE said that iodide could not be looked on as a specific in this disease. It was a curious fact that it was often most difficult to find the fungus in cases in which there was a large quantity of diseased tissue present.

Mr. HARRISON CRIPPS showed a Concretion removed from the rectum of a woman sixty-three years of age. She had suffered from almost constant diarrhœa, but had not had hæmorrhage. The concretion was removed by dividing the posterior wall of the rectum and extracting with a scoop. It weighed nearly half a pound, and was composed chiefly of carbonate of magnesium. No nucleus such as a gall-stone could be found. Careful inquiry failed to bring to light any article capable of producing the concretion in the previous diet of the patient, and she had taken no magnesia medicinally.—Dr. ORD showed some fragile calcareous concretions passed from the bowel by a patient. The abdomen was explored, but nothing was found but a dilatation of the sigmoid flexure. Dr. Ord also showed a calcareous concretion removed from the rectum of the guanaco.—Mr. W. G. SPENCER said that he had removed a similar concretion, which was composed of a nucleus of vegetable matter surrounded by many layers of calcareous material.—Dr. VOELCKER suggested that the calculi shown by Dr. Ord might have originated in the pancreas.

Mr. HARRISON CRIPPS exhibited a specimen of Cystic Degeneration of the Omentum which was removed from a woman. It was found unexpectedly during an operation for recurrent appendicitis. The omentum was converted into a cystic mass, and was removed through the wound, when it resembled a bunch of white grapes. No evidence of hydatid disease could be found, and he thought that the cysts were due to dilated lymphatics. They were lined by columnar epithelium.—Mr. EVE referred to a specimen in the Museum of the Royal College of Surgeons of England in which there were similar cysts lined by columnar epithelium. He agreed that they were probably dilated lymphatics, and similar to the dilated lymphatics containing chyle that were occasionally met with in the mesentery.

Mr. JAMES BERRY showed a specimen of Cystic Degeneration of the Great Omentum discovered accidentally when making a post-mortem examination of a woman who had died in St. Bartholomew's Hospital from carcinoma confined to the rectum. The peritoneum in most parts was healthy, but the presence of a few adhesions here and there in the abdomen indicated slight peritonitis at some bygone period. The great omentum presented a very remarkable appearance; it was much atrophied and contained no fat. It was represented mainly by a network of slender fibrous bands passing from the transverse colon to the sigmoid flexure, to which they were firmly adherent. Connected with these bands, lying between them and hanging from them, were numerous cysts or vesicles, all of which had exceedingly delicate and perfectly transparent walls and contained a pale yellow, slightly viscid fluid. The shape and size of the vesicles varied considerably, from the size of an egg to that of a pea. Most of the vesicles were at one end quite free, while at the other they were attached to the rest of the omentum by a narrow stalk. Mr. Berry was unable to offer any decided opinion as to the nature of the disease in his specimen, but from the exceeding delicacy of the cyst walls and from the tubular nature of many of the cysts he was inclined to believe that the cysts might be regarded as distended lymphatic vessels.

Mr. G. B SMITH and Dr. J. W. WASHBOURN described a series of Infective Tumours occurring in the Genitals of Dogs. A dog affected with a tumour on the penis served twelve bitches, of whom eleven became infected. Three of these bitches were then served by a second dog, who subsequently developed a growth on the penis. After becoming infected this second dog served two healthy bitches. One of these bitches developed a growth in the vagina while the other remained unaffected. A dog which was artificially

Hosted by Google

inoculated on the penis developed a growth similar to those in the above series. The tumours commence as minute translucent papules which grow slowly, and at the end of about twelve months are converted into lobulated masses. At a late stage the vagina may be filled with lobulated masses, which protrude from the vulva and distend the perineum. In the majority of cases there was no deep induration, and the tumour was readily removed from the subjacent structures with the mucous membrane to which they were attached. In two cases in which a post-mortem examination was made there was infiltration of the muscular wall of the vagina, and in one of these cases the lymphatic glands in the groin were affected. The microscopical structure of all the tumours examined was identical. It consisted mainly of cells of a rounded or polyhedral shape, in the latter case giving at first sight the impression of an epithelial new formation. A careful examination, however, proved that the cells were not derived from epithelium The stroma varied considerably in different growths, sometimes being scanty and sometimes relatively abundant. In the latter case the cells were enclosed in irregular alveolar spaces. There was nothing in the microscopical appearance of the tumours to distinguish them from the sarcomata met with in the human subject. The tumours were not due to irritation produced by discharge. In fact, in the majority of cases there was no discharge whatever either at an early or a late stage of the disease. There was no tendency to spontaneous cure; but when the tumours were completely removed at an early stage they did not recur. Attempts to infect rabbits and guinea-pigs failed. In two cases the tumours were successfully transplanted to the subcutaneous tissue of dogs. In conclusion, Mr. Smith and Dr. Washbourn gave reasons for believing that the tumours were of a similar nature to those described by Geissler, Wehn, Duplay, and Cazin in their work upon the infective nature of cancer. They had not yet been able to get conclusive results from cultivations from the tissues.

Mr. CECIL BEADLES showed a specimen of Tuberculous Peritonitis associated with an Inguinal Pouch of the peritoneum, which was taken from the body of an imbecile old woman who had symptoms of strangulated hernia. On operation an inguinal pouch was found filled with pus. The sac contained no bowel, but there was a mass which was either thickened Fallopian tube or broad ligament. The bowels were all matted together and drawn over to the right side of the abdomen.

Dr. JOHN FAWCETT showed a specimen of Hydrocephalus, with blocking of the posterior end of the aqueduct of Sylvius, which was apparently the direct result of a blow on the head.

Dr. SAMUEL WEST and Dr. F. W. ANDREWES exhibited a specimen of Rupture of a Healthy Œsophagus caused by Vomiting. The patient was a man fifty-five years of age, who was brought to hospital for acute pain referred to the left side of the chest and persistent vomiting. After death a long rent three inches in length was found in the posterior wall of the œsophagus near the cardiac end. There was dark fluid in the posterior mediastinum as high as the root of the lung and in the retro-peritoneal tissue below the diaphragm as far as the pancreas. There were also collections of brown fluid between the base of each lung and the diaphragm. There was no sign of previous disease of the œsophagus, and the rupture appeared to have been directly caused by the vomiting.

SOCIETY OF ANÆSTHETISTS.

A New Anæsthetic Inhaler.—Occurrence of Pneumonic Conditions after the Administration of Anæsthetics.

A MEETING of this society was held at 20, Hanover-square, W., on March 18th, the President, Mr. G. H. BAILEY, being in the chair.

Professor HOLIDAY (of the Royal Veterinary College) exhibited a New Anæsthetic Inhaler. The first apparatus, which was made for him by Messrs. Arnold and Sons of West Smithfield, consisted of a small bottle with a wide neck, to which was fitted a cork bored for the passage of two tubes. One tube, at the lower extremity of which was fitted a valve to prevent egress, allowed admission of air which passed over the chloroform in the bottle and took up vapour in its course, the other was for the exit of a mixture of air and vapour. To the latter tube was attached the extremity of a pair of rubber bellows, the action of which was to send vapour from the bottle and force it on towards a mask which fitted the patient's face. The amount of anæsthetic vapour admitted into the mask was regulated by a tap placed in the lower portion and by pressure upon the ball. In a room at a temperature of 60° F. with 6 drachms in the bottle, when the bellows were worked as much as possible there passed out of this at each pressure about two-fifths of a minim of chloroform vapour well mixed with three and a half ounces of air, thus giving a proportion of one part of chloroform vapour to 4200 parts of air. This proportion could be still further diminished to 1 in 8000 or even much less by having a mask with an open end (such as he used for the dog) or by putting a less amount of chloroform in the bottle at the commencement. The second apparatus was so devised that it forced a certain amount of air over the surface of the chloroform in the bottle, the proportion in this case being approximately (when six drachms were in the bottle and the room was at a temperature of about 60°) one part of chloroform vapour to 3000 parts of air, the apparatus sending out about half a minim of vapour at each pressure of the ball. This latter apparatus thus occupied a middle place between the first and Junker's (which forces air through chloroform). The advantages were that the chances of death from overdose were minimised (the strength of vapour and amount allowed to be inhaled could be regulated to a nicety), there was no fear of irritant or rubefacient effects on the face of the patient, the chloroform was less likely to become oxidised or otherwise changed (as may take place when air is bubbling through it), and also that the amount taken up from the surface was more constant than when air is forced through an ever-diminishing quantity of the fluid. In the case of the dog alone Professor Holiday said they had records of over 300 consecutive cases in which either one or other of the apparatus had been used without a single death which could be attributed to the chloroform, and in only three cases had they had to resort to the antidotal measures of hydrocyanic acid and artificial respiration. Recovery, too, was always tolerably rapid and unaccompanied by the nausea and depression which he had seen after administrations by the open methods. For the trial in human practice of the first form of apparatus Professor Holiday was indebted to several gentlemen, particularly Dr. Dudley Buxton, who kindly tested the first one which was made. All the gentlemen to whom he had submitted it spoke favourably upon its merits for children, parturition cases, and prolonged operations, but for adult men the vapour was apparently too much diluted. He was hoping, however, that the second form of apparatus would get over this difficulty and at the same time retain all the advantages.—Professor HOLIDAY also showed an arrangement for Passing Compressed Air from an Iron Bottle over the Surface of Chloroform for use either with the above or a Junker's inhaler.

Dr. SILK then introduced a discussion on the Occurrence of Pneumonic Conditions after the Administration of Anæsthetics, a *résumé* of which was published in THE LANCET of March 20th.—Mr. RICKARD LLOYD remarked that in consequence of the seeming opportunity for the spread of disease afforded by the repeated use of the uncleansed bag of Clover's small inhaler, he suggested in THE LANCET of May 28th, 1887, the use of a new or a thoroughly cleansed bag for each patient. The new bags appeared to be too expensive for general use. Messrs. Maw, Son, and Thompson made them of rubber at 9*d.* each, and Messrs. Barth, more successfully, of prepared paper, at 3*d.* or 4*d.* each. A week or two ago the latter firm thought it possible to produce the bags much cheaper. It had often occurred to Mr. Lloyd that more might be done to protect patients from possible chill about the time of operation and in the wards afterwards, as the risk of simple inflammation of the respiratory passages was greatly increased, if not solely induced, by this, and specific bacilli would find it a great auxiliary in the production of disease. He read extracts from the notes of Mr. C. H. Wilmer, house physician at the West London Hospital, of a case in which bronchitis, followed by left lobar pneumonia and left pleurisy with effusion, developed successively from the time of operation for removal of a broad ligament cyst in a pale, delicate-looking woman, twenty-four years of age. She ultimately recovered. There were no other cases occurring about that time in the hospital; and, indeed, bronchial irritation calling for treatment was in his experience rare, while he was unacquainted with any case of

Hosted by Google

pneumonia attributed to an anæsthetic, and the case cited was not apparently of specific origin.

ÆSCULAPIAN SOCIETY OF LONDON.

Exhibition of Cases and Specimens.

A MEETING of this society was held on April 2nd, Mr. STEPHEN PAGET, President, being in the chair.

Dr. R OSTLERE showed a man with red-brown Discolouration of the Skin of the Face and Forearms suggesting sunburn or Addison's disease, but really consequent on chronic eczema. The patient was an in-door worker. His general health was good and as far as was known he was free from constitutional taint.

Dr. L. U. YOUNG showed a case of large Intra-peritoneal Abscess with Visceral Fistulæ. This patient, a girl aged twelve years, had also been under the care of Mr. S. Paget and Mr. H. J. Waring. She came first under treatment with the abscess, which was believed to be tuberculous, discharging at the umbilicus. This was freely opened up and found to be intra-peritoneal and to communicate with an opening in the ascending colon. Later, a similar vesical fistula was also discovered. The colic fistula was converted into an artificial anus and the patient's general condition had since then much improved. No fæces had passed per anum for three months.

Mr. W. C. M'DONNELL showed a case of Lead Paralysis in a man who had nearly recovered under glycerine-tannate of iodide of potassium and Faradism.

Mr. S. PAGET showed:—1. A case of Lupus Infiltrating the Pinna of the Ear in a boy. 2. A case of Hermaphroditism in a child aged nine years. The penis was adherent along its entire under-surface dividing the scrotum into two pseudo-labia. The urethra opened at its base like a small vagina, coming out under the pubic arch. The testes were undescended. 3. A case of Well-marked Genu-valgum in a man almost amounting to Dislocation of the Knee-joint. (Both of these cases were under treatment in the Metropolitan Hospital).

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Epidemic of Small-pox at Gloucester.

A MEETING of this society was held on March 29th, Dr. G. P. BATE, President, being in the chair.

Dr. JOHN CAMPBELL read a paper on the recent Epidemic of Small-pox in Gloucester, of which city he was the medical officer of health. The population, he said, was about 41,000, of whom very few adults had ever been re-vaccinated, and since the guardians ten years ago ceased to enforce the Acts the great majority of the children, forming probably nearly a fourth of the inhabitants, had remained entirely unprotected. Indeed, the anti-vaccinationists boasted that Gloucester was the least vaccinated town in England and had enjoyed immunity from small-pox for twenty years. The death-rates for the three years preceding the epidemic had been 20·17, 15·34, and 18 46, and the zymotic rates 2·17, 1·29, and 1 65; while deaths from typhoid fever were few. So far from the epidemic being due, as the anti-vaccinationists alleged, to defective drainage, overcrowding, and insanitary conditions, the small-pox originated in, and was almost confined to, a district where the sewerage was excellent and the density of population 31·41 to the acre, but where there was the largest proportion of children nearly all unvaccinated; and the reason why it did not extend to the poorer, ill-drained districts, with 64·3 inhabitants to the acre, was obviously that so soon as the outbreak in the better part of the town assumed alarming proportions the panic-stricken people of the other districts crowded to the vaccination stations in thousands. The first cases occurred in June and July, 1895, but were concealed, no medical man being called in; others derived from these were notified in August and promptly removed to the hospital, the houses being disinfected, but others, described as measles, escaped notification. By the end of the year 26 cases had been notified, and probably as many concealed. The hospital accommodation was inadequate and no means existed for the disinfection of bedding. In January, 1896, the sanitary authority awoke to a sense of the danger, but the guardians, supported by an active anti-vaccinationist propaganda, remained passive for some time longer. The notifications, some dual, in January were 41, in February 150, in March 518, in April 783, in May 367, in June 112, and in July 23, after which there were no more. In February Dr. Bond, supported by Dr. Sweeting from the Local Government Board, brought the guardians to a sense of their duty. A Lyon's disinfector was set up, hospital accommodation was extended, and the additional vaccinators appointed by the sanitary authority were taken over by the guardians and placed under the supervision of Dr. Bond. Only 742 cases were received in the hospitals, the rest having been treated at home. There were 710 cases under ten years of age, of whom 23 had been vaccinated and 687 were unvaccinated. Of the former none, of the latter 278 died. Between ten and twenty years of age there were 309 cases; 260 vaccinated in infancy with 9 deaths, and 49 unvaccinated with 13 deaths. At ages above twenty there were 925 attacks, 889 vaccinated with 99 deaths, and 36 unvaccinated with 15. There were also 35 cases occurring in persons who were said to have been vaccinated in infancy, but who showed no marks; they were therefore practically unprotected, and 15 of them died. Not one of the nurses engaged in the hospitals or on the district staff was attacked, all having been successfully re-vaccinated, but all of those in the service of Mr. Pickering, an anti-vaccinationist, contracted the disease except one, who, having been previously on the hospital staff, had been re-vaccinated there. Of the 200 deaths occurring in the hospital 127 were of unvaccinated children under ten years of age, and the total mortality among patients of that age was 64 per cent., or nearly double what it had been in the previous epidemic, when a larger proportion of the children had been vaccinated.

A short discussion followed, in which Dr. SEATON, Dr. GWYNN, and the PRESIDENT took part.

Reviews and Notices of Books.

A Manual of Chemistry. By WILLIAM A. TILDEN, D.Sc., F.R.S., Professor of Chemistry in the Royal College of Science. London: J. and A. Churchill, Great Marlborough-street. 1897. Price 10s.

IT is a strong proof of the rapid progress which has been made in chemical science—and especially that part dealing with the inorganic elements—during the last quarter of a century that in the familiar work before us, which is based upon Fownes' original manual, revision has necessitated the re-writing of a large part of the existing matter and the addition of a considerable amount which is new even to the edition of it by the late Henry Watts. To Dr. Tilden's lot it has fallen to remove the last traces of the work of Fownes. We are glad, however, that he has found it possible to preserve the original form of the old manual. On turning over the pages without reference to its title chemists will observe at once the form and style of the old text-book which was their true and faithful companion in the days long since gone by. The book, of course, is brought well up to date, as instanced in the references to the work of Professor Smithells on the structure of flame; to Professor Clowes's new and ingenious method for the detection of inflammable gas in the air of coal mines; to the work of Professor Dewar and of Professor Olszewski on the liquefaction of oxygen, air, and hydrogen; and to the discovery of argon and helion by Lord Rayleigh and Professor Ramsay. Dr. Tilden has wisely added an introductory chapter on the most important historical events in the development of chemistry from the time of Boyle. Such a preface cannot but prove to be useful to the chemical student. The plan of the original work is also preserved. Thus the mathematical side of the science is deferred until the student is made familiar with the chemistry of the non-metallic elements and the facts concerned. On page 232 he commences the study of the principles involved. As we have indicated, the book is an admirable lecture and laboratory companion. We presume the present volume will be followed

Hosted by Google

by a second devoted to organic chemistry. In Fownes's manual both sections were dealt with in one volume, but in Watts's edition the book was divided into two volumes. We can gather no indication in the present volume that a second volume on organic chemistry is in preparation, although surely it would be justified since Dr. Tilden, in the preface, remarks, "This book is not intended for children." And organic chemistry is not an easy subject.

Lectures on Renal and Urinary Diseases. By ROBERT SAUNDBY, M.D. Edin., F.R.C.P. Lond. Second edition. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1896. Price 10*s.* 6*d.* net.

IN this volume Dr. Saundby has included the substance of his two monographs on Bright's Disease and on Diabetes, with considerable revision and addition. The result is a work which embraces questions of great pathological moment that have for long received much attention in the scientific world; and it is the product of one who has devoted especial care to the study of these subjects. The author is particularly mindful to assign credit for observations and opinions stated in the text, each chapter having appended to it a list of bibliographical references that prove the width of his reading and his anxiety to present the questions according to their most recent developments. A preliminary chapter on the Anatomy of the Kidney is followed by chapters on the Pathology of Albuminuria and on Dropsy. As regards the former we commend for particular notice by medical officers to insurance companies the statements that "albuminuria may be present in healthy persons for long periods without causing any derangement of the general health or of the structure of the kidneys," and that "albuminuria *per se* should not be regarded as an insuperable objection to life insurance." The present standpoint of the Pathology of Uræmia is well explained in the almost too brief exposition given in Chapter VII. A separate chapter is devoted to Retinal Changes in Renal Disease. Dr. Saundby's classification is suggestive and is based on etiological grounds. By it he divides the various forms of Bright's disease into (1) infective nephritis, comprising all cases due to infectious diseases, and including, therefore, most cases of acute parenchymatous nephritis, of chronic fatty kidney, and many of typical granular kidney; (2) toxic nephritis, which largely consists of cases of red granular kidney ("lithæmic" nephritis, as he elsewhere calls it) that occasionally, owing to intercurrence of acute attacks, may become enlarged and fatty; and (3) obstructive nephritis, that needs no explanation. This classification, though scientifically justifiable, yet has the drawback of referring anatomically similar lesions to separate heads. Lardaceous disease is kept apart, as it is not entitled to rank as a form of nephritis or Bright's disease. The chapters on Diabetes are full of interest, and on the whole they strike us as being more pervaded by the results of the author's personal observations than the other sections do. Nothing can be better than the descriptions given of the morbid anatomy of diabetes mellitus or the careful exposition of its clinical history, whilst the interesting subject of diabetic coma is amply and clearly discussed.

The Essentials of Chemical Physiology. By W. D. HALLIBURTON, M.D. Lond., F.R.S. London: Longmans, Green, and Co. 1896. Price 5*s.*

THE fact of a second edition of this essentially practical work being called for is evidence of its usefulness, especially as it differs little from the previous edition except in respect of the record of some recent advances and some small revision to increase its instructional value. It affords a handy companion for the use of students working at the physiological bench. Its contents amount to a series of lessons comprising an elementary and an advanced course. Each lesson is prefaced by practical directions for the experimental verification of the facts which are subsequently described. The tests thus enumerated bear the stamp of practical proof. In the appendix several well-known forms of physiological apparatus are described. We do not, however, find any mention of the application of Lovibond's tintometer to the estimation of the corpuscles and the colouring matter of blood. In a course of physiological chemistry such a book as this is indispensable.

LIBRARY TABLE.

Toxicology. Edinburgh: E. and S. Livingstone. Price 1*s.*— The interrogative method of teaching a subject is useful enough because, perhaps, it leads the student to think a little more than he would by merely reading. The little production before us is one of the catechism series. It is concise, to the point, and correct, but would have been improved if a little more system had been adopted in the arrangement of subjects. Of course, the book is not one for reference, but for rudimentary instruction; all the same, it would have been better if some sort of division had been made between the facts regarding one poison and those regarding another.

A Course of Practical Chemistry for Medical Students as Prescribed by the Conjoint Board. By CHAS. FREDERICK BAKER, Lecturer on Chemistry in Mason College, Birmingham. Birmingham: Cornish Brothers. 1896. Price 2*s.* 6*d.*— This book presents the usual deficiencies of those intended exclusively for examinational purposes. It is written within very close limits of the requirements of the primary chemistry examination of the Conjoint Board. Any modification that the Board of Examiners may choose to adopt will therefore soon render it valueless. As it is, the information given in regard to the specific reactions of a salt, with a view to detection, is distinctly meagre. The methods given for the preparation of various compounds are good and intelligible.

Chemical Notes and Equations. By G. H. GEMMELL, F.I.C., F.C.S. London: Baillière, Tindall, and Cox. Price 5*s.*— The student of medicine attending chemistry lectures for the first time frequently finds it useful to have recourse to a small book which will refresh his memory in regard to the facts he has had brought before him. The book before us supplies such a want, dealing, as it does, with brief notes on the various subjects, to which are added the principles involved in chemical changes and the equations representing them. It is impossible, however, to overlook a specimen of slipshod writing which is calculated to instil wrong ideas. Thus for the symbols of carbon, oxygen, sodium, and silver the author writes a mixture of wrong and hypothetical formulæ as follows: C_3 O_4 Na_2 Ag_2. We believe we are in agreement with the highest chemical authorities when we state that the number of atoms in the molecules of carbon and sodium, for example, and their molecular weight are not known with the certainty which this would imply.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The spring meeting of the South-western Division of this association is to be held at Barnwood House, Gloucester, at 2.45 P.M. on Tuesday, the 27th inst. Dr. Soutar invites the members to luncheon at 1.30. After the election of members and the transaction of business a discussion will be opened by Dr. Soutar on Recoveries in Asylums, to be followed by a paper by Dr. Goodall on the Systematic Collection of Anthropometrical Data in Asylums. The members will dine together at the New Inn Hotel at 5.45 P.M.

THE RESPONSIBILITIES OF PUBLIC BODIES.— Under this heading in THE LANCET of March 6th we recorded judgment at the Hants Assizes in favour of a gentleman living at Bournemouth, whose garden was overflowed with sewage from a drain of insufficient capacity. The matter has since been taken to the High Court, where Mr. Justice Vaughan Williams has confirmed the decision of the court below, giving judgment for the plaintiff on the findings of the jury.

Analytical Records
FROM
THE LANCET LABORATORY.

NEW TABLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, E.C.)

INTERESTING additions to the useful list of tabloids have recently been made in the following:—Tabloids of stypticin for administration both hypodermically and by the mouth in doses of one-quarter and three-quarters of a grain. Stypticin is the name given to hydrochloride of cotarnin, an oxidation product of narcotine; it appears to be allied in its therapeutic action as well as in chemical structure to hydrastinin, but as a uterine hæmostatic it is said to possess distinct advantages, since it is also sedative in its action. Eucaine hydrochloride is prepared in soloid form for the convenient preparation of a standard solution of the salt for producing local anæsthesia. Its action is similar to cocaine, but without its objectionable toxic effects. Tabloids containing five grains of trional are convenient for the administration of this comparatively new hypnotic. (As pointed out in a paper read before the Clinical Society by Dr. Rolleston and reported in THE LANCET of March 27th, the administration of this drug may lead to excessive urobilinuria.) An equally rapid hypnotic is tetronal, which is suitable, it is said, for prolonged administration. Further useful combinations in the form of tabloids are as follows: Quinine salicylate tabloids containing three grains of the salt which has been prescribed for influenza and in the treatment of rheumatic gout (the salt is insoluble in water, but readily breaks up in a slightly acid medium); compound bromide tabloids, containing the bromides of sodium, strontium, and ammonium, with a small quantity of arseniate of soda to obviate acne; codeine tabloids, containing each half a grain of the alkaloid; mercury with chalk and opium tabloids, for use in syphilis; blue and compound rhubarb tabloids, containing equal quantities of blue pill and compound rhubarb pill, and therefore useful as a cholagogue and purgative; compound iridin tabloids, containing iridin, extract of hyoscyamus and compound rhubarb, serving as a valuable combination, possessing alterative and cathartic properties; compound colchicum tabloids, containing one grain of the acetic extract of colchicum with one and a half grains of salicylic acid, the joint effect of salicylic acid upon febrile conditions and of colchicum in increasing secretions and diminishing arterial throbbing and relieving pain, rendering this combination of especial value in the treatment of gout and acute attacks of rheumatism. Lastly, two useful combinations of pepsin and strychnine, with and without bismuth, according to requirements, afford an excellent formula, in the treatment of atonic dyspepsia.

PURO TEA.

(THE SHANGHAI AND FOOCHOW ASSOCIATION, 22, FENCHURCH-STREET, E.C.)

Puro tea is offered to those who find ordinary tea indigestible or with whom tea generally disagrees. The leaf is treated with a small quantity of a solution of bicarbonate of soda and an alkaline salt, and then dried in a revolving drum in the ordinary way. The infusion accordingly is distinctly though not excessively alkaline, while the alkalinity of the ash obtained on incineration is, of course, somewhat above the average yield. The effect of this treatment would be obviously not to remove the tannin, but simply to neutralise it as a free acid and form a neutral and soluble tannate. It is probable that free tannin is accountable for the injurious effects of tea, since it would appear that when this tannin is neutralised the ordinary retarding effect of tea upon the digestion is entirely removed. The proportion of caffeine was normal. Puro tea may prove suitable in some cases where ordinary tea cannot be taken without discomfort, but not in all.

INFANTS' FOOD.

(THE BRITISH MALT PRODUCTS CO., 98, BERMONDSEY-STREET, S.E.)

This is a completely malted preparation, and therefore may be regarded as having been prepared in anticipation of the peculiar dietetic requirements of infants. It consists of brown brittle grains possessing a sweet malty taste, and is to a very large extent soluble. It is well adapted for the purpose of an infants' food when prepared with milk in suitable quantity.

WHOLE MEAL BREAD.

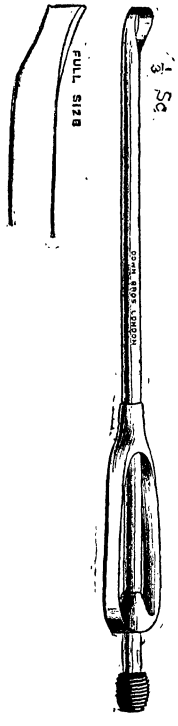
(CHAPPELL AND SONS, 132, HIGH-ROAD, KILBURN.)

On microscopical examination this bread proved to contain a mixture of cereals, each of which would contribute special food factors. Branny particles occur in a somewhat coarse condition, so that it is probable that the bread would have some irritating action upon the intestinal tract. The total mineral matters amounted to nearly 1·9 per cent., which is consistent with the statement that the bread was prepared with whole meal.

JYREE TEA.

(A. C. IRWIN AND CO., 40 AND 42, GREAT TOWER-STREET, E.C.)

Jyree is the name given to a tea composed of ordinary tea leaves mixed with the leaves of a certain Indian plant. The infusion of the leaf appears to have distinct sedative properties and also the property of counteracting the injurious effects of an ordinary over drawn or strong infusion of rich tea. The leaf is of a light green colour, very small, and not unlike the small leaves of the yew; it measures on an average about three-eighths of an inch long by not more than one-tenth of an inch broad. The leaves yield on infusion a dull yellow liquid, which turns to a bright yellow on the addition of an alkali. The infusion is pleasantly aromatic and slightly bitter to the taste, and it is possible that its soothing effects are due to a principle allied to the lupulin of hop, which is well known to promote sleep. On extraction with suitable solvents no definite principle was obtained, but a wax-like residue of peculiarly bitter taste and an aromatic oil. The infusion of the leaf is evidently rich in soluble nitrogenous matters, which are thrown partly out of solution on the addition of the tannin of tea, so that on adding an infusion of tea to the infusion of the Indian leaf a precipitate occurs, and this may account for the soft character of the infusion made from a mixture of the leaves with tea. The foreign leaves themselves, however, contain a variety of tannin. They appear to have been used with benefit as an application to wounds in reducing inflammation and in alleviating pain, and an alcoholic extract is prepared for medicinal purposes. From the accounts which are to hand from Indian natives of the virtues of the leaf of this interesting plant it would seem to deserve further and extended attention being given to it. Its admixture with tea to nullify the latter's astringent and harmful properties is a decidedly novel expedient, and we think far preferable to chemical treatment.



A NEW ISOLATION HOSPITAL NEAR WINCHESTER.

An iron isolation hospital has just been opened for the New Winchester Rural District Council on the downs to the east of the city. The building has been supplied by Humphreys of Knightsbridge, and consists of two principal wards 30 ft. by 20 ft., with matron's room and offices in the centre. The lighting is by hanging lamps, the ventilation is overhead, and the heating is by slow-combustion stoves. There are dry-earth closets with drainage in connexion. There has been extensive planting around the hospital, and the total cost has been £500.

Hosted by Google

New Inventions.

AN IMPROVED UTERINE FLUSHING CURETTE.

THE advantages of a flushing curette for the uterus are obvious, but those hitherto made have many disadvantages. Most of them do not give a good flush; in some the curette is too large compared with the diameter of the tube, and is hence liable to get "nipped" by the cervix closing upon the shaft. Even in the most modern forms the scraping edge is too extensive and liable to cause unnecessary laceration in a longitudinal direction. The instrument figured here is an attempt to avoid these drawbacks. It is simply a modified Barker's flushing curette made to a size to fit the uterus, and with two scraping edges at the end. The advantages are (1) a good flush; (2) the curette is only one-eighth of an inch wider than the shaft; (3) the scraping surface at the back of the curette enables a backward scrape to be given when dealing with the angles of the uterus without turning the instrument round; and (4) the flush is directed forwards by the anterior opening being larger than the posterior. The instrument was made from my drawings by Messrs. Down Bros. of St. Thomas's-street, London, S.E.

C. F. MARSHALL, M.D. Vict., F.R.C.S. Eng.
Lock Hospital, Harrow-road, W.

REPORT ON LEPROSY IN NEW SOUTH WALES FOR THE YEAR 1895.[1]

THIS Report contains clinical and etiological notes by Dr. Ashburton Thompson on the cases of patients admitted during the year 1895 in the lazaret for New South Wales, and notes on the histo-pathology of the tissues of patients who died in 1895 by Dr. Frank Tidswell. These reports have a special interest. In New South Wales an attempt is being made to restrict the spread of leprosy by compulsory isolation of lepers, and, as this is a measure which is urged on all civilised Governments who have lepers amongst their subjects and is likely to be more and more strongly urged, the experiment deserves careful study, particularly by Englishmen who are responsible for the government of India, where up to the present time there has been no efficient control of lepers and where spread by contagion is untrammelled. The care, sometimes excessive, with which the law is administered in New South Wales is evident from a consideration of these reports.

A woman consulted a practitioner on account of an affection which he believed to be leprosy, and he reported her under the Leprosy Act. She had given a false name and address, but was soon discovered. Her sister, who was a leper, lay concealed at the time in the same house. The patient was admitted to the Coast Hospital for observation, but her regular attendant maintained that she was not suffering from leprosy. The signs of leprosy were not considered to be sufficiently objective and she was not detained. Subsequently, in January, 1896, she consulted her regular attendant and two other medical men were called in consultation, one of whom reported the patient as a leper and described unmistakeable symptoms of leprosy, but she had again given a false name and address, and was not again seen in New South Wales. She was next heard of as a patient at University College Hospital in London![2] This history shows the difficulties inseparable from the administration of the Leprosy Act, but it also shows the necessity for restriction. The two leper sisters were the children of Irish parents. The question of heredity cannot come in, and, considering the very small number of lepers in New South Wales, the probability that the one was infected by the other is so strong as to be practically certain.

Another case is interesting. The patient, a man, aged forty-nine years, and a native-born white of New South Wales, presented the following symptoms. The right hand was analgesic. The cubital nerve, although not enlarged at and below the notch, was easily perceptible far upwards, and was therefore enlarged from that point. On pressure, sensation was limited to the fourth finger only. The left hand was also analgesic, although sensation was not so much disturbed as in the right. The ulnar nerve was large, but not hard. There were scars of recent blisters on both hands, and there were also scars on and below the right patella which were analgesic. The feet were also analgesic. In the left lower extremity there was a cluster of scars on and below the patella, which were analgesic. On the plantar aspect of the foot, at the base of the fourth and fifth toes, there was a dry, shallow and nearly insensitive ulcer, surrounded by much thickened cuticle which shelved down to the surface of the sore, marking the site of an old blister. There was a smaller ulcer on the heel of this foot. This foot was more analgesic than the right. Under pilocarpin the feet, hands, forehead, and right chin remained perfectly dry, while the rest of the body sweated freely. Dr. Ashburton Thompson naturally considered this to be a case of pure lepra nervorum—an opinion shared by other medical men—and the case was reported under the Act. It being the custom to seek a second certificate from a practitioner not in permanent relation to the Government, such a gentleman was requested to examine and report. As he was unable to satisfy himself that the disease presented was leprosy, and as the patient claimed discharge, the law giving no power to detain suspects, he was allowed to depart. This case shows the care that is taken in Sydney to secure the rights of suspected lepers. Any physician who has a practical knowledge of leprosy will have no doubt regarding the nature of the disease in this case.

Two other cases of a somewhat similar nature were diagnosed by Dr. Ashburton Thompson as cases of nerve leprosy, and the symptoms reported seem to us to completely justify the diagnosis; but two other medical men called in separately, although they considered it most probable that the disease was leprosy, declined to certify under the law. These two patients were children of the same parents, natives of New South Wales, of English descent, and resident in Sydney. In another case the patient, of English and Irish descent, was born in New Zealand, but was taken to Fiji when she was two years old. When she was twelve years of age her left forefinger became sore. It got well again in a week, and the occurrence would not have been remembered but that it was immediately followed by severe aching pains in the arm and by wasting and loss of power in the hand. Leprosy developed, and she died from that disease in September, 1895.

The reports on the histology of the fatal cases are full and careful, and will interest pathologists who specially occupy themselves with studies of the leprosy bacillus. Twelve well-executed micro-photographs are appended to the Report, in which many changes produced by the development of the bacillus and the bacillus itself are well shown. We would specially call attention to a most excellent photograph of the bacilli in serum expressed from a tubercle, magnified 1000 diameters. This photograph shows a large number of the leprosy bacilli very distinctly, and in excellence we have rarely seen it equalled. Dr. Tidswell is to be congratulated on the success which has enabled him to give the profession these excellent photographs. On Dec. 31st, 1895, there were thirty-seven lepers in the lazaret. Sixteen of them were whites, of whom four were females; the remaining twenty-one were members of various coloured races.

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1897.

THE Hospital Reform Association has appointed a committee to inquire into the working of special hospitals in London, and the report of this committee will be found on page 1041. It is an interesting document, and shows that the newly formed Association perceives the responsible nature of the work that it has assumed. For in these critical times for hospitals it is necessary to recognise, firstly, their value, and, secondly, the danger that there is of their altogether losing their original character and with it their claims as charitable institutions of the first order. It must be remembered that this report deals only with special hospitals — institutions of comparatively recent growth, but so numerous and in some cases so pretentious as to threaten seriously the prosperity and the very existence of the general hospital, which in its catholicity embraced all cases and preserved the broad character of medicine and surgery. It is gratifying already to see in several directions indications of a reaction against specialism. In general hospitals and in private practice men are everywhere being trained whose readiness in different emergencies rebukes those who would restrict their practice to this or that branch of medicine.

Our readers will study the report for themselves, but we must emphasise a few of the chief facts which it brings out, and may be allowed a preliminary word of praise in reference to the tone of moderation which characterises it. The authors seem ready to admit, if not the virtues of special hospitals, at least the virtues of those who represent them. If they point out in clear words the reluctance of some officials to give information as to their institutions, they are equally ready in other instances to acknowledge candour and willingness where they have met them. Hospital abuse is not to be removed by random and reckless censure. Some special hospitals have justified their existence by their work, and have put the great general hospitals of the country on their mettle, leading them to introduce into all their work provision for the special case. Let us now come to some of the individual facts which the report brings out. Looking especially at the financial system on which a large number of these hospitals are worked, we find that they are largely dependent on the payments of patients. Of the forty-one special hospitals visited, at least thirty receive direct payments from their patients, the receipts from this source amounting in 1895 to £24,085. The authors of the report significantly tell us that over half of these institutions obtain more money from patients than from annual subscribers. One institution receives twenty-five times as much from its patients as from its subscribers. At St. John's Hospital for Diseases of the Skin the payments of patients (out-patients from 1*s.* to 2*s.* 6*d.* weekly, in-patients 15*s.* weekly) amount to £2263, while annual subscriptions amount to only £773; at this institution the secretary showed every willingness to answer questions. At the Central London Ophthalmic Hospital more than half the income is derived from patients. At the Hospital for Diseases of the Throat, Golden-square, patients in 1894 paid £2858 and the annual subscriptions amounted to £286. At one hospital it is open to the medical officers to see private patients, and it was not easy to ascertain who decided which were private and which were hospital cases. The questionable nature and influence of these hospitals is further shown in the petty nature of the sums charged per visit to out-patients. Thus at the Central London Ophthalmic Hospital out-patients are charged 2*d.* a visit, while the system of inquiry into their circumstances is stated in the report to be merely nominal. At St. Peter's Hospital, with £2186 derived from patients' payments and £250 from annual subscriptions, the authorities appear by the report to be accommodating in their charges to out-patients, who may be called upon to pay on a sliding scale from 6*d.* to 1*s.* or 10*s.*

The conclusion is irresistible from these facts, unless the report can be gainsaid, that at these institutions charges are made which would bring any private practitioner into discredit, and that medical and surgical practice is carried on in unfair competition with the general practitioner. What would be thought of any private practitioner who pretended to supply skill and medicines for 6*d.* or even 2*d.* a visit? Yet here are hospitals, in some cases officered by gentlemen of the highest reputation, which, according to this report, enter into wholesale competition with private practitioners, and secure patients, it would seem, by the lowness of the fee demanded. The time will come when our consulting brethren will refuse to be made the tools of such a ruinous and demoralising system. The report concludes with sundry recommendations for the amendment of these evils, such as the insistance on a wage limit, with occasional departures from it at the discretion of a competent inquiry officer; the total abolition of the system of subscribers' letters; more care on the part of subscribers, and especially of the Hospital Saturday Fund, in the gifts of such letters as they have. Like ourselves, the Association looks with confidence to the staffs of the hospitals to help to avert the ruin alike of the truly charitable institutions and the profession at large by the monstrous system of indiscriminate and inefficient relief which now prevails.

DURING the last few years the relations existing between the epidemiologist and the oyster have not, it is to be inferred, been of the most cordial description, and although the oyster, owing doubtless to its high value both financially and gastronomically, has borne the chief brunt of the attack, it cannot be said that certain other shell-fish, such as mussels and cockles, have come out of the ordeal to which they have been subjected altogether unscathed. For many years it has been matter of common knowledge and experience that certain persons and families possess a peculiar susceptibility with regard to mussels, and numerous instances are on record in which the consumption of this

Hosted by Google

mollusc in an uncooked condition has been followed by serious and often fatal manifestations of ptomaine poisoning. Within recent years, however, evidence has been accumulating which tends to incriminate mussels as being at times responsible for conveying enteric fever, and in the recent Local Government Board report on "Oyster Culture in Relation to Disease" Dr. BULSTRODE has contributed a chapter in which he shows, after discussing its natural history and distribution, that the mussel is at times gathered from localities dangerously near to sewer outfalls, and that there is need for some control in reference to mussel "lays" and "gardens."

We note that Dr. RIDLEY BAILEY, medical officer of health of Bilston, in his current annual report which has just been issued, records an interesting instance in which four persons, visitors to Blackpool, were seized with symptoms of ptomaine poisoning shortly after consuming raw mussels procured from the vicinity of a sewer outfall, and two of these four persons subsequently developed enteric fever at such a date after the ingestion of the mussels as to render it highly probable that the shell-fish were the means of conveying the disease. These facts were reported to Dr. JASPER ANDERSON, medical officer of health of Blackpool, who stated that there were at that place in October last no less than six cases of enteric fever which had apparently been caused by the ingestion of raw mussels procured from a bed where sewage contamination was a matter of probability. Dr. ANDERSON very properly had notices placed on the mussel beds warning the public as to the danger of consuming the fish. We learn, too, from the Local Government Board reports that in 1883 Dr. M. K. ROBINSON, medical officer of health of the East Kent Combined District, reported two case of enteric fever contracted from consuming raw mussels procured from a locality liable to sewage pollution, and that in 1894 Dr. F. C. H PIGGOTT of Teignmouth and Dr. NEWSHOLME of Brighton reported cases where the evidence pointed strongly in a similar direction. Ptomaine poisoning as the result of eating mussels dates back, however, considerably earlier than 1883, and it is recorded that in 1827 some thirty persons were attacked with serious symptoms, which in two cases ended fatally, after eating mussels collected from the dock gates at Leith, and animals to which some of the mussels in question were given were similarly affected. Amongst other disasters of a like nature may be mentioned that of Wilhelmshaven, where the mussels which caused the mischief were procured from the bottoms of two vessels in the harbour; and in 1890 there occurred what was known as the "Seapoint calamity," in which a mother and four children died from the effects of eating mussels procured from a locality to which sewage had access.

There is still much to be learnt in connexion with the subject of mussel poisoning, but it is obvious that there are other factors than idiosyncrasy involved. It is generally considered that the poisonous effects are due to what is known as *mytilotoxin*, a poison produced by the agency of bacteria which have as a rule been conveyed to the mussels through the sewage pollution of the water in which they have grown or been placed; and although there would seem to be certain instances on record in which sewage could hardly have polluted the water, a large number of outbreaks have been caused by mussels taken from places liable to pollution of one kind or another, and there is thus clearly need for some control of the mussel industry. There would seem to be no very satisfactory evidence pointing to copper as the cause of the peculiar symptoms observed, as in the Leith instance Dr. CHRISTISON analysed some of the mussels taken from the stomachs of persons attacked, but was unable to detect a trace of the metal in question, while it appears that in some instances copper could not possibly have gained access to the bivalves to which the illness was traced. It is a difficult matter to prevent mussels from growing in the vicinity of sewers, and it is also difficult to prohibit excursionists and others from helping themselves to such mussels; but it would certainly seem that sanitary authorities in whose districts are mussel "scalps" liable to sewage pollution should take steps such as have been taken by Dr. ANDERSON at Blackpool, and in any subsequent legislation on this subject powers might be conferred to prohibit the laying down of these molluscs in unsafe positions. The cooking of all mussels intended for human consumption would doubtless do much to remove the risks of contracting enteric fever, but this process would not be equally effective against ptomaine poisoning. In this latter connexion it may be of practical utility to record that in the Wilhelmshaven outbreak, which was investigated in one or another of its aspects by numerous observers, amongst whom were VIRCHOW and SALKOWSKI, it was discovered by the latter that *mytilotoxin* became inactive when treated with carbonate of soda, and that mussels boiled for some six minutes in a solution of this salt lost their toxic properties—a fact which appears to afford indication for treatment in cases of poisoning by mussels.

THE literature on the health of the soldier in India has grown until it is impossible to deal with it in its entirety, Happily, there is not any need to do so, for the facts and the moral they convey are comparatively plain and simple, and as they are quite capable of being understanded of the people there is a general consensus of opinion that something has to be done to check the evil. Two ways of dealing with this form of contagious disease have been proposed—namely, that of the Secretary of State in his despatch to the Government of India regarding the measures to be adopted for checking the spread of venereal disease among the British troops in India, and that of "The British Committee of the Federation for the Abolition of the State Regulation of Vice" in a published document which strikes us, we confess, as in some respects a feeble and jejune production manifesting but little acquaintance with human nature or the Army. What is the practical good of a Select Committee going again into the fundamental constitution of the British Army? The broad facts are admitted, and the case as it stands has to be met by some practicable remedial measures capable of speedy application. It puzzles us, as it does most people, to understand how the presence of disease is to be ascertained without examination. If the abolitionists of the State regulation of vice, as they are pleased to style themselves, have no more plausible, practical, and unobjectionable measures to suggest in the way of remedy

Hosted by Google

than those they have put forward in their circular we do not think they will obtain the support of many sensible people. Lord GEORGE HAMILTON rests upon a firm foothold of facts, and the position he has taken up in his despatch is a logical, well considered, and studiously moderate one. HER MAJESTY'S Government, recognising the extent of the evil, its appalling increase of late years, its increasing virulence, and the way in which the health of the civil population, and of subsequent generations in this country, is imperilled by the annual discharge from the Army of men constitutionally diseased, cannot acquiesce in the continuance of the existing state of things. The Government considers that the cantonment rules laid down in the Act of 1889 should not merely be applicable to "cholera, small-pox, diphtheria, or typhoid fever," but to all contagious and infectious diseases, including venereal disease. We may parenthetically remark that the Indian Government has quite recently passed an Epidemic Diseases Act for the express purpose of dealing with the present epidemic of plague. Now plague is a very rare and occasional visitant of that country, and, however infectious and fatal it may be, it is not an hereditary malady; whereas the scourge of syphilis is permanently present, it is eminently contagious and hereditary, it gravely affects the constitutions of those attacked by it for long periods of time, it overlaps and complicates the course of other diseases, and very often involves the innocent and is transmitted to the unborn. It follows, therefore, by a parity of reasoning, that in these respects syphilitic disease calls for the application of preventive measures quite as much as plague. If the State owes it as a duty to its subjects to interfere with their liberty in order to protect them against disease in one case, it does so in the other. But to return to the Government despatch. The Secretary of State mainly adopts and follows the recommendations of the memorandum of the Army Sanitary Commission on the subject. He calls upon the Government of India to consider the whole question and to forward a copy of the draft rules proposed to be issued in order to give effect to the decision of HER MAJESTY'S Government. We quite appreciate the need which exists for the Government proceeding warily if they are to avoid giving "occasion for the enemy to blaspheme" in a matter about which so much ignorance, prejudice, and false sentiment prevail. But it cannot be said that the Government has not safeguarded the moral aspect of the question, or that the measures proposed in the official despatch are not of a most moderate and reasonable character.

The whole question is eminently one on which the members of the medical profession are qualified to speak, for they best know the gravity of the case; and the Royal College of Physicians of London and the Royal College of Surgeons of England have, most properly, in the interest of public health and in the cause of humanity—and especially as far as the unfortunate women are concerned—done what it was their plain duty to do to strengthen the hands of the Government in this matter. It is really a national demand that an earnest attempt should be made to deal with what amounts to a national scandal. We do not think that we can do better than summarise the recommendations and suggestions that have been already put forward, with such additions as occur to us. In the first place it must be frankly recognised that venereal disease belongs to the category of contagious and preventable diseases, and we are consequently bound to take what steps we can to prevent it. Women in a diseased condition should not be allowed to propagate contagion, but be required to go to hospital or leave the cantonment, and the measures that are necessary to prevent women from spreading contagion are, of course, applicable to soldiers under the same circumstances. The examination and treatment of females should be conducted by trained members of their own sex under medical supervision, in order to lessen or remove objections in this respect; but it would be well that medical officers who have the treatment of soldiers of the European Army should be also connected with the hospitals for female cases. And, in view of the importance of detecting and treating these diseases in their earliest and initial stages, means should be taken to secure that soldiers suspected of concealment, and those who have suffered from venereal disease, should be subjected to inspection—the latter for a year after infection.

Not only should soldiers arriving in India be systematically warned of the serious risks they incur, but it would be well to have a pamphlet printed and distributed among them, showing in a very simple way the extensive prevalence of venereal disease in India, giving plain and terse statement as to the lamentable and far-reaching consequences likely to ensue, and emphasising the great importance of early treatment when the disease has been contracted. This having been done, it might subsequently be worth consideration whether soldiers suffering from this malady might not be subjected to some pecuniary fine or loss, the proceeds to go to the benefit of the corps to which they belonged, and not to the State. Such a regulation, however, would enhance the risks of concealment. The powers of the commanding officer to place suspected places out of bounds, to prevent the employment of female labour in cantonments and women lurking about their vicinity, should be enlarged, and the cantonment magistrate should, as far as possible, aid in these efforts. It is worth considering whether the bazaars could not be placed in charge of some native contractor accustomed to oriental life and habits, who should be held responsible to the local European authorities for the proper conduct of the bazaar, and who could act in concert with such authorities in any repressive measures that might be deemed expedient. It is scarcely necessary to add that every care should be taken to make the hospitals for the treatment of females comfortable, and to secure for the patients humane, considerate, and kindly treatment, in order to induce them to recognise and desire to reap the advantages they afford. Finally, we consider that, after all, the most important point is to give the authorities in India a free hand in this matter, with the view of devising some scheme and the machinery for working it; otherwise they cannot accomplish an object so eminently necessary on the grounds alike of justice and humanity.

ROYAL INSTITUTION.—The following are among the lecture arrangements after Easter: Dr. Ernest H. Starling, three lectures on the Heart and its Work; and Professor Dewar, three lectures on Liquid Air as an Agent of Research.

Annotations.

"Ne quid nimis."

THE WORKHOUSE INFIRMARY NURSING ASSOCIATION.

IF Boards of Guardians would only realise that whatever tends to promote the rapid recovery of the sick under their care, tends also to diminish the length of time a sick pauper remains dependent on the rates, they would surely appreciate the great work which this association has done for them and for the sick poor committed to their care. Surely if they could once be made to grasp this obvious fact they would be induced to contribute more liberally than is indicated in the annual report of the philanthropic association now before us. The paltry one, two, or three guineas which these bodies contribute each year is wholly out of keeping with the benefits they receive in return and inconsistent with the hundreds of pounds spent for other purposes less necessary and less advantageous. The association depends entirely upon voluntary contributions for support, and the training of every nurse supplied costs, if our information be correct, approximately 21 guineas. Surely it would not be too much to ask the guardians to contribute a portion of this sum for every fresh nurse supplied to them. It is the bounden and fundamental duty of the guardians of the poor to provide for the sick poor, and we fail to see why a philanthropic public should be called upon to discharge the duties which properly belong to these officially appointed representatives of the ratepayers. Year by year the difficulty experienced by guardians, especially in provincial and rural districts, in procuring good nurses becomes greater. The openings for trained nurses are constantly becoming more numerous, and the conditions of workhouse and infirmary nursing certainly do not become more attractive. We hear of guardians advertising again and again without result. Some of these boards then apply to the association, in the report of which we read: "There have been 130 applications for nurses, and 73 nurses have been appointed during the year"; and, again, "Twenty-four boards have applied to us for the first time, but only twelve of these have been supplied with nurses." Now, why is it that hardly more than half of the applications have been responded to? Here is the answer: "Financial statement.—Unless we receive more support our training must be further diminished." We commend this matter earnestly to the attention of the guardians, in view of the extreme importance of having properly trained nurses for their sick, especially when the medical officer is non-resident, and in view of the economy to the rates which may be effected in the more speedy and successful cures. Some of the boards show their appreciation of the efforts made by the association on their behalf by waiting some months for its nurses. Something, however, must be done to meet this steadily declining supply of good nurses. Why do not some of the boards join hands with each other and with the Nursing Association to organise a central training school of their own? Meanwhile, surely, it is not too much to ask of the guardians of the poor that they will, for each trained nurse supplied, contribute, say, half the cost of her training—10 guineas—leaving philanthropy to do the other half. It is with no sudden impulse that we make this suggestion. We have watched with considerable attention the growth of the Workhouse Infirmary Nursing Association, and now and then have criticised its methods; but it has stood the test of time and the most searching investigation, and we confidently believe that no more suitable body could be entrusted with the work referred to. It is true that something might be done to increase the attractiveness of workhouse and infirmary nursing in one or two directions. The first of these is to give the nurse a more clearly defined position in her work and make her more directly responsible to the medical officer. The other is to raise the salary and emoluments to a degree commensurate with the monotony and drawbacks of the work. The Metropolitan Fever Hospitals, acting on this principle, give adequate salaries and never want for candidates. But unless the guardians take these matters into their earnest consideration, and adopt some such action as that which we have above suggested, the evils referred to will become steadily worse and worse, and by-and-bye we shall find that we have reverted to the condition of things revealed in the inquiry initiated by the Founder of THE LANCET half a century ago. We have received a copy of the return made to the House of Commons showing the proportion of sick to the nurses and pauper helps attendant on them, and this we propose to notice in a future issue.

PROFESSOR R. KOCH'S FURTHER RESEARCH ON TUBERCULIN.

NO one conversant with the thoroughness of all Professor Koch's work will have been surprised at the announcement that, undaunted by the comparative failure of tuberculin as a remedial agent, he should have been engaged during the seven years that have elapsed since he made his discovery known in endeavouring to determine the causes of its failure and to obtain a product which should be free from the drawbacks of the glycerine extract. For the details of the method which he at length arrived at and the ingenious processes it embraces we may refer to the account given by our Berlin correspondent. Suffice it here to say that they aim at separating the bacillary substance into two components, one of which, containing ingredients soluble in glycerine, has the properties of the original "tuberculin," producing marked reaction in tuberculous subjects and setting up changes around tuberculous foci. The other constituent, mechanically separated from the former, contains ingredients which are mostly insoluble in glycerine and also differs from the other moiety in its physiological action, only producing reaction if given in large amount. But this new product, the "tuberculin remainder," or "TR," as he terms it, is found to possess marked "immunising" effects, and its administration is proceeded with in gradually increasing doses until immunity is obtained. Professor Koch has not published these researches before being enabled by extensive trials to pronounce very definitely upon the superiority of the new preparations, and the results they produce in cases of tuberculous disease. It is noteworthy that he speaks with commendable caution as to the permanency of the results he has obtained, and he thinks that it may be possible to produce a lymph of still greater efficacy. We are glad to observe that he lays stress on the fact that these remedies are only efficacious in the early stages of tuberculous disease, a fact which was largely lost sight of in the former therapeutic trials, which ended perhaps in too sweeping a condemnation of the remarkable agency which Professor Koch had discovered. It is not unlikely that, as one consequence of the inconsiderate and irrational manner in which the use of tuberculin was then adopted, the improved lymph may not for some time be tried on a sufficiently wide scale to judge of its efficacy. Nevertheless Professor Koch's persevering labours and the knowledge that he would not venture to recur to the subject without good cause must have weight, but we trust that those who do make trial of the remedy will

Hosted by Google

strictly adhere to the conditions which he lays down and will, moreover, keep careful and accurate records of the cases so treated.

ENGLISH-MADE THERMOMETERS.

IN our remarks upon this subject in THE LANCET of March 27th we expressed our opinion that the most reliable mercurial thermometers were of English manufacture, and that distinct confirmation of this was afforded in the fact that in the Kew verifications the returns showed that the corrections were seldom two-tenths different from the graduated mark. We should point out, however, that owing to a clerical error we stated in the article referred to that the average deviation is never more than one degree, whereas it should have been two-tenths of a degree. We have received this week a beautifully mounted thermometer from Mr. Hicks in substantiation of the case he originally made out in regard to the accuracy of English-made mercurial thermometers. It registers from 20° Fahrenheit up to 100°, and is evidently suited, therefore, for the gauging of the temperature of the living room or of a sick-room or hospital ward. The corrections to be applied to the scale readings are, according to the determinations by comparison with the standard instruments at Kew, as follows: At 32°, −0·0°; at 42°, −0·0°; at 52°, −0·0°; at 62°, −0·1°; at 72°, −0·1°; at 82°, −0·1°; and at 92°, −0·0°. The instrument is graduated into unit graduations Fahrenheit, which are divided again into two-tenths of a degree. The accuracy of a thermometer is, of course, of the utmost clinical importance, and the point raised by Mr. Hicks as to the greater constancy of English glass in regard to contraction is one entitled to consideration. We should like to know what Mr. Hicks's actual experience is in regard to the slight diminution of bore which the tube of a thermometer undergoes after a time, and what is the usual extent of the error thus involved.

SANITARY MEASURES IN THE DIAMOND MINES.

IN an exceedingly interesting lecture delivered recently by Professor Crookes he refers incidentally to the subject of the environment of the native workers in the South African diamond mines. It cannot be doubted that there is every necessity for this class of labourers to be watched over in regard to hygienic conditions. For instance, we are told that "all below ground is dirty, muddy; grimy, half-naked men, black as ebony, muscular as athletes, with perspiration oozing from every pore, are seen in every direction, hammering, picking, shovelling, wheeling the trucks to and fro, keeping up a weird chant which rises in force and melody when a titanic task requires excessive muscular strain—the whole scene is far more suggestive of a coal mine than a diamond mine. And all this mighty organisation, this strenuous expenditure of energy, this clever, costly machinery, this ceaseless toil of skilled and black labour going on day and night, is just to win a few stones wherewith to deck my lady's finger." Professor Crookes, however, does not go so far as to say whether this employment is made as healthy as possible for the employés. It is true, as he says, that every kind of recreation seems to be provided for them, and in cases of accidents or illness there is a well-appointed hospital, where the sick are attended and medical supervision, nurses, and food are supplied free by the company. There is, of course, some amount of preventive treatment in the provision of recreation, but on the whole the measures would seem to be curative rather than preventive. Seeing the wealth of material they turn out, the labourers deserve every care at the hands of their masters. In regard to this wealth of material there can be little doubt, since "from two to three millions of carats of diamonds are turned out of certain mines in a year, and as five million carats go to the ton this represents half a ton of diamonds. To the end of 1892 ten tons of diamonds had come from these mines, valued at sixty millions sterling. This mass of blazing diamonds could be accommodated in a box 5 ft. square and 6 ft. high." Professor Crookes looks back with pleasure upon the Arabian Nights vision of the strong-room of one of the biggest companies which he visited, which was "literally heaped with stones won from the blue ground, purified, flashing, and of inestimable price, ready to play their part in the lives of men and women." We need hardly add that the discourse dealt with some interesting facts on the properties of the diamond. Perhaps the most remarkable physical property next to refraction is that of becoming phosphorescent after exposure to the sun's rays, one green diamond in particular in Professor Crookes's collection giving, as he stated, a pale green, almost white, light as brilliant as a candle flame. It was also pointed out that the x rays may be used very successfully in discriminating between imitation and real diamonds, the former being perfectly opaque and the latter extremely transparent. We found some months ago, when experimenting with "paste" and real gems, that this difference could be distinctly seen on the fluorescent screen.

IRON STAPLE IN THE ŒSOPHAGUS; REMOVAL AFTER LOCALISATION BY THE ROENTGEN RAYS.[1]

WE recently published two cases in which by means of skiagraphs halfpennies were diagnosed impacted in the œsophagus, and their removal was effected.[2] This case is more important because in the absence of the exact diagnosis furnished by the skiagraph, on the one hand, the most disastrous laceration might have followed attempts at removal in the ordinary way by the probang; or, on the other hand, the operation of œsophagotomy might have been unnecessarily performed. A man, aged sixty-nine years, was in the habit of swallowing his food after very slight mastication, in consequence of the absence of his molar teeth. Whilst eating a piece of mince-pie he was conscious for a moment of a hard substance in his mouth. Agonising pain followed, which radiated from the entrance of the œsophagus outwards and upwards along both sides of the neck and appeared to be caused by two sharp points which pierced the tissues with each attempt at deglutition. The pain, though much lessened in intensity, remained the same in locality and character until the foreign body was removed two weeks later. On the evening of the first day laryngoscopic examination showed that the normal contour of the arytenoids and aryepiglottic folds was lost, and that the area presented a confused mass of œdematous tissue which obscured the view into the larynx. Dyspnœa was slight, although distressing when an attempt was made to probe the œdematous area even after the free use of cocaine. The voice was husky and weak and interrupted by severe paroxysms of coughing. An enormous quantity of thick, ropy, clear-coloured mucus welled up from the œsophageal region of the pharynx, and blood oozed from the region at the back of the larynx. Neither by laryngoscope nor palpation could a foreign body be detected. The patient was first fed upon milk and then upon soft food, hashed meat, eggs, &c. The œdema subsided, and on the tenth day a small rounded substance was seen behind the right arytenoid. It resembled the elbow of a bent piece of heavy wire. A blunt hook was passed around it, but it was found to be firmly adherent. It was readily grasped by Cuscoe's forceps, but all the force that could be used failed to move it. Skiagraphs showing antero-posterior and lateral views were taken. The

[1] Bliss: International Medical Magazine, March, 1897.
[2] THE LANCET, Jan. 30th, 1897, p. 313.

Hosted by Google

object seemed to be the frame of a buckle, and lay diagonally across the œsophagus, mainly to the right of the median line, about in front of the fourth cervical vertebra. It was then possible to remove it with the laryngeal forceps. It proved to be a meat staple, unusually large, such as are used for fastening cards of address on meat. It consisted of a body an inch in length, which bore at each end an arm at right angles to it half an inch in length, the whole thus forming three sides of a rectangle. The arms were extremely sharp and ragged, and were firmly attached to the anterior wall of the œsophagus behind the arytenoid and cricoid cartilages.

SOLID SOLUTIONS.

IT is practically accepted now that the interesting class of bodies known as alloys are simply the solution of one metal in another. Some interesting experiments on this subject were shown in a lecture by Mr. C. T. Heycock, F.R.S., at the Royal Institution on the 2nd inst. The fact that when a weak solution of permanganate of potassium is frozen the ice yielded is quite colourless, so that the salt becomes concentrated, is probably true also for metals, and further confirmatory evidence is gained in the following ingenious experiment devised by Mr. Heycock and his co-worker Mr. Neville. If a solution of gold in sodium be allowed to solidify slowly the appearance of the block, or a section of it, would be quite uniform to the eye—that is, the gold, apart from the sodium or *vice versâ*, would be indistinguishable to the eye. By taking, however, a shadowgraph of the section by means of the x rays, a photograph is obtained showing the actual structure of the alloy, the sodium being transparent to the x rays while the gold is opaque. From the way the two metals are disseminated in crystalline form through the mass as it becomes solid a remarkable analogy evidently exists between the behaviour of an alloy and a solution in the act of solidifying.

WATER-SUPPLY AND SEWERAGE OF SYDNEY.

THE eighth annual report of the Sydney Board of Water-Supply and Sewerage states that during the eighteen months from Jan. 1st, 1895, to June 30th, 1896, the average amount of water supplied daily was 16,645,014 gallons; the estimated population using the water was 408,282, so that the average daily consumption per head was 40·76 gallons, as against 34·23 gallons in the year 1894. During the same period more than ninety-nine miles of new mains were laid, and 1438 houses were connected to the water-supply, making a total of 85,059 houses at present supplied, and a total length of 891 miles of water-mains, exclusive of trunk mains. The supply is derived from the Nepean River and two of its tributaries, the Cordeaux and Cataract Rivers, the catchment area being about 354 square miles. From the intake the water is led for a distance of about forty miles through open canals and tunnels to the first reservoir, which is called Prospect Reservoir and is about twenty miles from Sydney. The monthly analyses show the quality of the water to be excellent; the total solid residue, dried at 220° F., varied between 5·8 and 6 6 grains per gallon, the chlorine "as chlorides" varied between 2·3 and 2·6 grains per gallon. For water supplied for domestic purposes otherwise than by measure the charge is 10*s.* per annum for lands and tenements assessed at £17 and under, 7*d.* in the £1 for assessments from £17 to £300, and slightly reduced rates for higher assessments. Public hospitals and charitable institutions have a free supply limited to fifty gallons daily for each resident in the former and thirty gallons for each in the latter. The water revenue for the year ending June, 1896, was £174 357, and the expenses, including maintenance, management, depreciation, and interest, were £182,075, so that there was a deficiency. The returns of the sewerage department show that during the eighteen months 22½ miles of sewers were laid by the board and 5½ miles by the Government, making a total of 230 miles of sewers now under the control of the board. There are two outfalls, one discharging into the open sea and the other on to a sewage farm. About two years ago the board made over the farm to a lessee for a period of ten years, but it was worked in an unsatisfactory manner and the board exercised their power of re-entry for breach of the conditions of the lease. The daily discharge on to the farm is 2,059,000 gallons, which are disposed of over 65½ acres of land. The effluent runs into Botany Bay. The sewerage rate is 10*s.* per annum for premises assessed at £17 or under, and 7*d.* per £1 for assessments over £17. The accounts show that the sewerage revenue for the year ending June, 1896, was £85,486, and the total expenses, including maintenance, management, depreciation, and interest, were £98,749, so that there was a deficiency of £13,263. A report prepared by Mr. T. M. Kendall, medical adviser to the board, gives some statistics for the year 1895 relative to the prevalence in Sydney of some zymotic diseases more or less dependent on faulty drainage or the consumption of impure water. The population of the "metropolis"—i.e., the combined city and suburbs—was 423,000; the total deaths were 5549 (or 130·7 per 10,000), including 297 from diarrhœa, 88 from diphtheria, and 81 from enteric fever. The last-mentioned disease unfortunately increased in the beginning of 1896, and during the six months ending June 30th, 1896, it caused 102 deaths. The lowest temperature for the year 1895 was 36·8° F., registered on July 9th, and the highest was 96·8° on Dec. 16th; the greatest daily range—viz., 31°—occurred on Nov. 7th. The weather was extremely hot in the beginning of 1896, a temperature of 108·5°, which was the highest ever recorded in Sydney, having been reached on Jan. 13th. The greatest daily range for the first six months of 1896 was 32·2°, which occurred on Jan. 16th, when the temperature was 105·2° at midday and 73° at night.

"THE EDUCABILITY OF THE NERVOUS SYSTEM."

THE above was the title of an able and original scientific paper read by Dr. Rorie of the Dundee Royal Asylum at a recent meeting of the Naturalists' Society of that city. Professor Waymouth Reid occupied the chair. The experience and authority of the lecturer on the subject of psychology lent additional value to an excellent contribution, which was received by an appreciative audience with evident approbation. The text was set out in the following principles: "Can the functions of the nervous system be raised by care and steady diligence to a higher standard than would appear at present to hold ground? In other words, Could the present mental and moral standard of the human subject be raised by the improvement and education of the nerve cell; and, secondly, would mere neglect in the regular exercise of the various nerve centres—allowing these to sink into a state of atrophy—result in moral and intellectual degeneration?" In elaborating his theme the lecturer proceeded to give a lucid explanation of recent additions to the knowledge and functions of the nerve cells, illustrating his remarks by means of a large series of diagrams; their structure and development and the importance of a healthy nutrition were fully explained. It was also pointed out how periods of mental depression and barrenness and states of activity and fruition were in their turn to be traced to the exhaustion and recuperation of the nerve cells respectively. The condition of the nerve-cell in relation to the development of insanity and its bearing upon the elucidation of many most important points connected with criminal anthropology were touched upon. In conclusion, Dr. Rorie

Hosted by Google

stated that the latent capacities of individuals were in the majority of cases, if not in all, far beyond what are usually reached, and that the possibilities of increasing and developing these to their full extent depended on raising the vitality of the nervous system to its highest degree. In every individual vast numbers of cerebral cells probably remained undeveloped, and although as yet no nerve centres had been found corresponding to our knowledge of good and evil, of justice and benevolence, of purity and veracity, it could hardly be doubted that these had correlative neural equivalents equally with the mental and intellectual faculties, and they were therefore as much worthy of careful training.

ROYAL COMMISSION ON TUBERCULOSIS.

SITTINGS were held at 7, Whitehall-place, on April 1st and 2nd, Sir Herbert Maxwell, Bart., M P., being in the chair The other Commissioners present were Dr. R. Thorne Thorne, C.B., F.R.S., Professor G. T. Brown, C.B , Mr. Shirley F. Murphy, Mr. J. Cooke Trench, and Mr. J. Speir, The evidence was heard of three of the gentlemen nominated by the Cattle Diseases Committee of the Central and Associated Chambers of Agriculture—namely, Mr. B. St. John Ackers (chairman), of Gloucestershire, Mr. T. Carrington Smith, of Staffordshire, and Mr. J. Kay, of Lancashire. The evidence of the witnesses had reference, amongst other points, to the nature of the disease, its extent in various herds of cattle, and to the loss inflicted upon dairy farmers and agriculturists generally by its prevalence. The view was expressed that a stamping-out process, such as has been practised in the case of cattle plague, foot and mouth disease, and pleuro-pneumonia, was not applicable to tuberculosis, but that compensation should be given to the owners of animals which when living were apparently healthy, but which after slaughter were condemned and confiscated in the interests of the public health by reason of the presence of the disease.

THE CHEMICAL SOCIETY.

THE proceedings of the Chemical Society, as becomes the now largest affiliated branch of the Royal Society, are invariably conducted with due decorum and with but little excitement. The annual meeting of the Fellows on the 31st ult. was, however, an exception, on the occasion of the election of a new president in succession to Mr. Vernon Harcourt. The council had recommended Professor Dewar, but for some reason a good number of the Fellows took objection to the council's recommendation and put forward Professor Ramsay to represent them in his stead. This amounted to a vote of censure on the council's discrimination, and so there were important issues at stake, and in consequence there met together a record gathering of the Fellows. The method of ballot led to considerable confusion and discomfort. It consisted in the Fellows coming forward to the table and placing a voting paper in the basket watched over by the scrutators, and giving in at the same time their names. This procedure leads, of course, to the gathering of a crowd round the tables, to gain access to which is a struggle and for a voter to resume his own seat even worse. It would be much simpler, and certainly more comfortable, if the scrutators were to go round with their baskets while the company remained seated. The result of the election proved in favour of Professor Dewar, although, through some doubt as to certain of the votes being invalidated, the actual numbers were not disclosed. The President-elect occupied the chair at the annual dinner in the evening, when there were several distinguished representatives of science present. Amongst these was Lord Lister, who, in proposing prosperity to the Chemical Society, remarked on the enormous growth of the society, which was a fact curiously in contrast with the doubt that had been expressed by a scientific man at the time of its inception as to whether chemistry was a subject which would sufficiently occupy the attention of a society. The society's rooms at Burlington House were now becoming insufficient for the purpose. Other toasts were proposed by Professor Crookes, Dr. Gladstone, and Dr. Russell, and amongst those who replied were Professor Michael Foster, Sir John Evans, and Professor Thomson.

TREATMENT OF CHOREA BY EXERCISES.

As until recently in heart disease the value of rest was well recognised, whilst that of exercise was overlooked, so in other diseases in adopting one principle we thereby often fail to see that its opposite may also have an application. Most practitioners would insist on rest in the acute stage of a case of chorea that was at all severe, but they would never think of treating the chronic disease otherwise than by drugs, though gymnastics are not ignored in the list of remedies of the text-books. In a recent number of the *Canadian Journal of Medicine and Surgery* (March, 1897) Dr. M'Kenzie and Dr. Galloway bear testimony to their value which is decidedly convincing. A boy, aged eight years, the subject of chorea, came under treatment for lateral curvature of the spine. He was permitted to join a gymnastic class and take light work. At first he could not make the required movements, but he was allowed to continue and do the best he could. After the first lesson it was evident that the incoördination was less marked. The exercises were continued daily, and in less than a week every sign of chorea had disappeared. The treatment was tried in three other cases. In two no improvement occurred, but the circumstances were very unfavourable, and the patients only remained in the class a short time. The third was a girl, aged eleven years, who had suffered from chorea for two years, and had ceased to improve for several months, though under competent supervision. After three weeks' treatment careful examination revealed only an occasional slight incoördinate movement of the right foot in walking.

ELECTRIC LIGHTING IN MANCHESTER.

SOME remarkable statements were made at a recent meeting of the City Council showing the rapid growth of electric lighting in Manchester. Plant was put down in the first instance to last, as was thought, for three years. In five months the plant was increased sufficiently to last, as was expected, twelve months, but it only sufficed for seven months. Alderman Higginbottom, chairman of the Electric Lighting Sub-committee, said: "Beginning with a capital of £120,000, they had increased it to £300,000, and that would be gone this year, and in another six months they would have to come to the council for another quarter of a million for new plant." They began with 8000 sixteen-candle lamps three years ago. Now there are over 70 000. It appears to be profitable to the city, for in the first year expenses were covered, and in the second a handsome profit was made. Last year £11,000 of the profits were given in aid of the rates, and the cost to consumers was reduced 25 per cent., while this year it is said the cost will be reduced by another 25 per cent., and a larger sum given to the city in reduction of rates; and in a few years, Alderman Higginbottom added, "the new light will be within the reach of every man." So much has the undertaking increased that a new committee has now been formed—the Electricity Committee—"to deal with all matters arising under the Electric Lighting Acts, 1882 and 1888." In spite, however, of the extension of electric lighting, the consumption of gas steadily increases, and the Gas Committee will still have enough on their hands to occupy their best energies. The use of gas for cooking and in various ways for heating purposes, as well as for gas engines, is every day

Hosted by Google

becoming greater, and will do something to lessen the canopy of smoke which too often broods over Manchester.

THE ILLNESS OF MR. J. B. BAILEY.

WE regret to announce that Mr. J. B. Bailey, the librarian of the Royal College of Surgeons of England, is very seriously ill. Mr. Bailey has been well known for some years to readers in the library of the College, and many of the medical profession have reason to be grateful for the help which he was always so ready to afford to those who stood in need of it.

THE STRUCTURE OF NASMYTH'S MEMBRANE.

CONSIDERABLE light has been thrown on the structure of Nasmyth's membrane by the recent researches of Mr. Paul of Liverpool. Hitherto this tissue has generally been regarded as a thin layer of cementum, but from Mr. Paul's specimens there seems to be but little doubt that it is at any rate epithelial in character, and therefore in all probability a remnant of the enamel organ. He has shown that the membrane is composed of two layers, the outermost being composed of large flattened epithelial cells, beneath which is a thin, translucent pellicle usually marked with hexagonal impressions derived from the ends of the enamel prisms. Mr. Tomes, who has been the principal advocate of the cementum theory, has, in a letter in a recent issue of the *Dental Record*, acquiesced in the views held by Mr. Paul.

STREET NOISES.

EASTBOURNE is once more to the fore in the suppression of street nuisances. This time newsboys were in trouble. Five or six shouting together were said to have been heard at a distance of 300 yards. Five of the lads were defended, it being argued that it was an idle suggestion that vendors of newspapers could not cry in the streets. The by-law was directed against continuous calling or shouting, and it was submitted that unless the shouting was deliberately and in such a manner as to cause annoyance there was no offence. The bench were of opinion that the by-law was reasonable and that there was no doubt the shouting—in one case it was 6 o'clock A.M.—was a nuisance. They expressed an opinion that this was more the case in a town where there were many invalids, such as Eastbourne; and, while discharging the lads with a caution, they hoped their employers would give them such instructions that they would not again get in trouble. We in London are still patiently awaiting legislation of this kind.

INTESTINAL IRRIGATION.

IN a paper in the *New York Medical Journal* of March 13th Dr. R. C. Kemp discusses the various uses of rectal irrigation and describes a double-current irrigator which he uses for this purpose. The apparatus is essentially the same as that of the ordinary rectal douche, with the addition of a double-current tube, which varies from four to fourteen inches in length, the latter size being flexible. This method, as the writer allows, is not novel, and it derives its chief interest from the fact that in Dr. Kemp's hands it has been made to serve a great variety of purposes and has on the whole fulfilled his expectations of its value as a means of treatment. As in using the ordinary enema, the patient's position is carefully adapted to the end to be served and the part of the colon to be reached by irrigation. A variety of mild antiseptic solutions are employed. Among the diseases said to have been thus treated successfully are, besides ordinary fæcal obstruction, colitis (simple and membranous), gastro-enteritis, dysentery, and typhoid fever. Shock, uræmia, and hæmorrhage appear to have been distinctly benefited by this means, warm, or in the last case hot, saline solutions being used. Relief has in like manner been afforded in cases of pelvic peritonitis, cystitis, and inflammatory trouble in the prostate and adjacent structures. By means of an apparatus which, like this, allows the return of the fluids injected irrigation can be so carried out that as much as several quarts may be passed into and more or less freely ejected from the colon. We observe that Dr. Kemp has used the irrigator very freely in such diseases as dysentery and typhoid fever, and apparently with advantage. We cannot but think, however, that in morbid conditions like these, associated with inflammation and usually also with ulceration, irrigation might easily be overdone and prove injurious. The purpose in view is antiseptic and so far logical, but it were surely best to limit the use of the douche to the early stages of these diseases and to, at most, a few occasions. Then, too, it should prove of especial value by removing septic and irritant matter and so reducing the dose of morbid poison in the bowel. Its administration under such conditions is certainly suggestive, and may very probably aid in abating the severity of the enteric disorder.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

THE festival dinner of this institution, over which the Duke of Connaught presided, at the Hôtel Métropole on Friday, April 2nd, cannot be said to have been a success if the amount subscribed on the occasion is not supplemented by further donations. The sum of £10,000 is urgently needed for the purpose of (1) re-arranging and enlarging the out-patient department, (2) the acquisition of an open space to be used as an airing court for male patients, (3) some improvement in the accommodation provided for the nurses, and (4) the completion of the building fund of the new country and convalescent branch at Finchley. Yet in spite of His Royal Highness's eloquent appeal the secretary was able to announce only the small sum of £3000 as a result of the dinner. As His Royal Highness said, "this hospital was started thirty-five years ago, and during this time it has steadily advanced in utility. It treats diseases which are exceptional and require exceptional treatment, and not only does it require that patients shall be kept in the hospital for three months or six months, but sometimes for a year, and even on the completion of that long time they are often unfit to take part in any of the public duties of a citizen. It is therefore of especial value that not only should inmates be treated for their terrible diseases, but that some proportion of them at least should receive pensions to enable them to live after treatment."

ADULTERATION, UNWHOLESOME FOOD, AND MARGARINE.

MATTERS connected with the purity of food-supply are coming very prominently before the public at the present time. This may be mainly accounted for by the strong efforts which are being made by certain of our legislators to push through the proposed new Food and Drugs Bill, which is to strengthen the hands of those entrusted with the duty of keeping our daily food free from objectionable admixture. There would be little difficulty in carrying out effectively the provisions of the present Act if all offences were of the remarkable character of an instance reported last week. Certain grocers in the Battersea district were convicted for selling as arrowroot an article containing 100 per cent. of borax, and as sago an article containing 100 per cent. of tapioca. The blame was attached to a young assistant (how often the young assistant is made the scapegoat) who had failed to distinguish the articles. The possibilities of this gross want of acumen on the part of the young assistant are

Hosted by Google

appalling. It is fortunate that he did not substitute something worse, although even in the case of borax mischief might have been done. In a district not far off a pastry-cook was found premeditating the admixture of unsound condensed milk, which was totally unfit for the food of man, with certain other materials for the preparation of "pound" cakes. Some of the tins were without labels and "blown." It is evident that the tricks of unscrupulous persons have not been entirely suppressed, as some would have us believe. It is for those forms of fraud, which have now grown so ingenious, that the provisions of the new Act have been principally strengthened. The margarine fraud is one of them. The law very properly requires the seller to call margarine by its proper name, and to sell butter as everybody understands that term, without any admixture with foreign fats. No one can doubt the wholesomeness of margarine as a food, but when butter is demanded pure butter alone should be supplied. The margarine industry objects to certain clauses of the proposed new Act on grounds the logic of which we fail to see, and this position is well defined by a writer in the *Times* of April 2nd.

THE SALE OF POISONS.

THAT the law is not always logical was very well illustrated in a prosecution at Heywood last week, when a chemist and druggist was charged with selling poison—namely, strychnine—to a person unknown to him, and who was not introduced to him by a person of whom he had knowledge. A woman asked for rat paste, but he could not supply it, and instead gave her vermin killer. On her return journey home by train the woman swallowed the preparation, and death eventually took place. The defence was that rat paste was quite as deadly as vermin killer, but it did not come under the schedule of the Act. The defendant was convicted and fined ten shillings and costs. It is the same old story. The Act, in attempting to provide against the indiscriminate sale of poisons fails in a great measure because it is not sufficiently comprehensive or stringent. We have had more than enough evidence lately to prove the necessity of placing several poisons within the meaning of the Act that are at present not so classed. Apart from the injury done to the community, these omissions make it unnecessarily difficult for the pharmaceutical chemist to conduct his business comfortably and legitimately, since, there is reason to suppose, he is just as anxious to comply with the requirements of the law as any other erson. Still, in the present case the druggist committed an offence by neglecting to sell a scheduled poison in the prescribed way. The rat paste would have done the same mischief, but then he would have been free from blame. Bumble surely would have been right in his opinion of the law in this case.

"GAS BACILLI" AND PUTRESCENCE IN UTERO.

DR. G. W. DOBBIN reports a case of puerperal sepsis, due mainly, he considers, to the bacillus aerogenes capsulatus.[1] The patient, a multipara with generally contracted pelvis, had been in labour two days with a child of large size, and was under the care of a midwife. On approaching the bed a sweetish, offensive odour was perceptible and the maternal genitals emitted a bubbling, crackling sound, whilst the vaginal discharge contained many gas bubbles. Delivery was accomplished with the Tarnier basiotribe, under chloroform. Immediately after it there was an explosive escape of sickening fœtid gas from the uterine cavity. There was as yet no tissue emphysema. Next morning "gas bacilli" were found in the tissues of the fœtus and in the placenta, and the same evening the mother died. A few hours later the body was enormously swollen and emphysematous all over. The fœtus and the placenta were likewise infiltrated with gas, which burnt with a flame when ignited, and was infested everywhere by the "gas bacilli" along with staphylococci and streptococci. The placental bloodvessels contained gas cysts surrounded by a zone of these bacilli, cultures of which were made. A pigeon and a rabbit were inoculated and rapidly developed an œdematous emphysema. These observations are in accord with those of Welch and Nuttal,[2] who attributed many cases of supposed entrance of air into the uterine sinuses to this parasite. They also found that this bacillus when inoculated into rabbits was not usually fatal, but that if the animal were then killed the micro-organism developed rapidly with abundant formation of gas in all organs. Dr. Dobbin argues that in his case the bacilli were introduced by the nurse; that they found in the dead fœtus, as in the dead rabbit, a suitable nidus, and filled the uterine cavity with putrid gas; and that the mother died not infected by the bacilli, but poisoned by the toxins produced by them, her own macerated vaginal tissues, moreover, acting as a seat of germ development. Whether this explanation be in all points correct or not, the case itself should serve to accentuate the danger of delay in cases of prolonged and difficult labour.

[1] Johns Hopkins Hospital Bulletin, February, 1897.

DEATH UNDER NITROUS OXIDE AND ETHER DURING A DENTAL OPERATION.

AN occurrence so unusual requires careful examination. Has the feeling of security which has grown with regard to this combination since Mr. Clover first introduced it into common practice been a delusion, or is some explanation at hand? The report of the death from a lay contemporary[1] states the facts as follows. The patient, a woman aged twenty-nine years, had been a nurse and was an able-bodied woman free from organic disease, but as she suffered from neuralgia the removal of several stumps and teeth was considered advisable. Mr. Arthur Vernon Evans, M.R.C.S., L.R.C.P., administered nitrous oxide gas and ether, and "about one and a half drachms" of ether were used. We may presume that an inhaler was employed. The dentist had removed three teeth, when Mr. Evans observed that the patient's face changed colour and that the pulse ceased. Prompt removal from the chair and the performance of artificial respiration with hypodermic injection of strychnine failed to restore animation. Death, it was thought, took place three minutes from the appearance of collapse. A necropsy was made, which showed the organs to be uniformly healthy. It seems hardly likely that ether played any part in the catastrophe. The inhalation of about ninety drops would produce an almost inappreciable effect. There appears little doubt that the case was one of simple cardiac syncope occurring during the state of recovery from a light anæsthesia. The assumption, which appears in the evidence, that nitrous oxide acts as a cardiac depressant is, of course, not generally admitted, and, as is well known, syncope under that agent is most rare. What happens in some cases is that an impediment to expiration exists—such, for instance, as the forcing back of the tongue during the extraction of lower teeth, dropping of the jaw, or the faulty position of the patient's head, and this leads to the patient being unable to rid the circulation of the gas which has been inhaled. This will produce syncope and death. The danger of such a proceeding has only to be pointed out to be avoided. It is no exaggeration to say that nitrous oxide gas has been given many millions of times and with impunity, and is being

[2] Ibid., August, 1892.
[1] The *Windsor and Eton Express*.

Hosted by Google

so given thousands of times daily. Perfection in anæsthetics has yet to be found, but it may fairly be claimed for nitrous oxide that it has stood the test of time well and may still claim for its title "the safest of anæsthetics." It must be understood that nitrous oxide anæsthesia is not asphyxia; the one condition is associated with increased vigour of the heart's action, the other rapidly leads to paralytic distension of the blood-vessels owing to impeded circulation through the lungs.

THE PLAGUE ON BOARD A BRITISH TRANSPORT.

THE *Dilwara*, hired transport, bringing troops from India, arrived at Southampton on April 6th. This is the vessel on which a case of fatal plague occurred on March 18th. On reaching Suez the persons who had been in immediate contact with the deceased child were landed at Moses' Wells, disinfection was carried out, and the vessel was allowed to pass through the Suez Canal in quarantine—that is to say, with guards on board to prevent communication with the land on either side. Before the arrival of the ship at Southampton Dr. Bulstrode, of the Medical Department of the Local Government Board, went down to Southampton to confer with Mr. Harris, the port medical officer of health, and to arrange with the naval and military authorities as to the landing of some 1200 men, women, and children on board, and he remained there to watch the disembarkation of the troops, &c. All necessary arrangements were completed before the arrival of the vessel, and, in accordance with English practice, no persons were detained, since all were healthy on arrival. The arrangements at Southampton, which are largely due to Mr. Harris's admirable initiative, sufficed for all purposes; and since no fresh cases had occurred on board nothing but medical inspection and certain measures of disinfection were necessary. This case proves anew how easy it is, with proper sanitary administration and healthy conditions on board, to deal with and to prevent recurrences of plague, and it also justifies the action laid down by the Local Government Board in dealing with this disease, which was formerly subject to quarantine at our ports. This is the third vessel reaching an English port in which there has been plague derived from Bombay, and in no case has there been any extension of the disease.

A CLINICAL meeting of the Neurological Society of London will be held at the rooms of the Medical Society, 11, Chandos-street, W., on April 22nd, at 8.30 P.M. Members wishing to show cases are invited to communicate with one of the hon. secretaries, Dr. F. W. Mott and Dr. J. S. Risien Russell, as soon as possible, and are requested to send to 4, Queen Anne-street, W., very short abstracts dealing with the salient features of the cases.

THE Hospital Reform Association will present its memorial against hospital abuse to the Royal College of Physicians of London in a few days' time, so that members of the profession are invited to sign it without delay. At the meeting of the Council of the Association held on April 1st it was decided to prepare a memorial on hospital reform for presentation to H.R.H. the Prince of Wales.

UNDER the auspices of the American Surgical Association and the Alumni Association of the Jefferson Medical College of Philadelphia the statue of the late Professor Samuel D. Gross, M.D., will be unveiled near the Army Medical Museum, Washington, D.C., on Wednesday, May 8th, 1897.

INFANTILE MORTALITY IN EGYPT.

A CORRESPONDENT, who has been examining the weekly statistical returns issued by the Egyptian Sanitary Department, has tabulated a summary of the facts relative to the deaths of children during each quarter of the year 1896; and the results, which are shown below, may be correctly described as appalling.

Place.	Quarter of 1896.	Deaths. Under 1 year.	1 to 5 years.	Over 5 years.	Percentage. Under 1 year.	Under 5 years.	Remarks.
Cairo.	First ...	1194	1216	1710	29·0	58·5	Deaths from cholera excluded.
	Second ...	1763	1922	1861	31·8	66·4	
	Third ...	2052	1378	1605	40·7	68·1	
	Fourth ...	1239	1305	1593	29·9	61·4	
	Total ...	6248	5821	6769	33·2	64·0	
Alexandria.	First ...	588	469	819	31·3	56·3	Ditto.
	Second ...	769	559	859	35·1	60·7	
	Third ...	1031	601	744	43·3	68·6	
	Fourth ...	822	581	766	37·8	64·6	
	Total ...	3210	2210	3188	37·2	62·9	
Eighteen towns in Lower Egypt.	First ...	772	590	1129	30·9	54·6	Deaths from cholera included.
	Second ...	1075	1072	1696	27·9	55·8	
	Third ...	1495	1643	2173	28·1	59·0	
	Fourth ...	935	1166	1259	28·4	62·8	
	Total ...	4307	4471	6257	28·6	58·3	
Eleven towns in Upper Egypt.	First ...	624	383	857	33·4	54·0	Ditto.
	Second ...	838	818	1280	28·5	56·4	
	Third ...	886	915	1727	24·9	51·4	
	Fourth ...	842	820	788	34·3	67·8	
	Total ...	3190	2966	4652	29·5	56·9	

The unavoidable inclusion of the cholera deaths in the portion of the table referring to the provincial towns has the effect of making the infantile death-rate appear to be more favourable than was actually the case, for judging by Cairo and Alexandria the number of young children carried off by the epidemic must have been comparatively small; but even as they stand the figures represent a terrible preponderance of premature mortality, no fewer than sixty out of every hundred burials having been of children under five years of age. Compared with the births this slaughter of the innocents comes out in, if possible, a worse light, as will be seen by the subjoined table.

Deaths per 1000 Births.

—	Cairo.	Alexandria	Eighteen towns in Lower Egypt.	Eleven towns in Upper Egypt.
Under one year ...	237	279	241	273
One to five years	267	192	250	254
Total	554	471	491	527

In the former table one of the most noteworthy features is the progressive increase in the mortality up to the end of the third quarter. It is not until the Nile rises and washes away the impurities that the death-rate begins to diminish.

THE HOSPITAL REFORM ASSOCIATION.

REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON.

To the Council of the Hospital Reform Association.

GENTLEMEN,—In pursuance of your instructions to inquire into the working of the special hospitals of London we have personally visited forty-one institutions, which has necessitated about eighty separate visits, besides numerous letters. We herewith append in tabular form the specific details required of these institutions. In the following remarks we abstain as far as possible from mentioning individual institutions. Unless otherwise specified, all the details in the table are taken from the published hospital reports for the year 1895. With few exceptions we were well received and the information for which we asked was readily given. We have nearly always interviewed the secretaries, and in some cases we have also seen members of the visiting staff or officials in charge of the out-patient departments. In many cases the secretaries recognise the possibility of abuse; in very few instances was its existence absolutely denied. It should be borne in mind that in all cases our information has been obtained from interested parties. There are several points to which we wish to draw attention in detail.

1. *Subscribers' letters.*—Out of the forty-one hospitals ten do not issue letters, and of the remaining thirty-one only six rigidly enforce their use. Some of the smaller institutions appear to use letters to enable them to obtain a grant from the Hospital Saturday Fund.

2. *Payment by patients.*—Thirty-two hospitals receive payment from their patients, collecting a large sum annually (£24,085 in 1895). We would point out that this amount is earned entirely by the work of the medical staff, who receive no portion in return. More than half (eighteen) of these institutions obtain more money from their patients than from their annual subscribers; in some cases as many as from ten to twenty-five times as much. On comparing the patients' payments and annual subscriptions for these thirty-two hospitals we find that these received £7000 more in patients' payments than in annual subscriptions in 1895. We cannot refrain from drawing attention to the fact that at one institution the average sum received for treatment from each paying out-patient is 11*s.* 9*d.* The payments are often made to subordinate officials, and no register or check is kept.

3. *Inquiry as to the means of patients.*—At fifteen of these institutions there is practically no inquiry at all, patients being admitted unquestioned, so that anybody may apply for, and will as a matter of course receive, treatment. Where an inquiry exists it is for the most part inefficient and wrongly directed. It partakes, as a rule, of one of two characters, either (*a*) How much can the patient pay the hospital? or (*b*) Can the patient pay a specialist's fee of one or two guineas? In neither instance is the patient asked if he or she could afford to pay the fees of a general practitioner. The inquiry is usually of a most cursory nature; the word of the patient is accepted, and no steps are taken to verify the statements. In other cases we found that although the letters contained spaces for the insertion of wages, means of livelihood, rent, &c., these particulars were neither filled in nor the questions asked. At some hospitals it appeared to be the custom to put upon the medical staff the duty of deciding the eligibility of the patients. We consider this to be unfair and unadvisable. This work is obviously outside the duty of the visiting staff, who as a rule have much more to get through than they can conscientiously do in the time at their disposal. Besides, it involves a personal element. If a medical man tells a patient he can afford to pay a practitioner it is equivalent to saying to the patient, "You can consult me at my own house." Even at those hospitals which profess some form of inquiry it is unusual to ask any questions of patients bringing a subscriber's letter for fear of offending the subscriber, and still rarer of those patients bringing letters from the Hospital Saturday Fund. We had repeated statements from the hospital secretaries as to the unsuitability of many of these latter patients for hospital treatment.

4. *Limitation to the speciality for which the hospital nominally exists.*—This limitation is fairly well enforced. However, at some chest hospitals large numbers of cases of anæmia and dyspepsia are treated; the Cancer Hospital treats abscesses, syphilis, and piles; and at women's hospitals generally the cases are by no means all obstetric in character.

5. *Limit to the number of new cases in the out patient department.*—Only two have a fixed limit. In the majority the attendance is small, but there are undoubtedly cases of overcrowding. The new patients on one day at the following hospitals are: No. 11, occasionally fifty; No. 22 an average of from thirty to forty; No. 3, from thirty to fifty; No. 10, from twenty-five to thirty; and No. 6, from twenty to thirty. Many of the cases treated at these special hospitals are of a common nature, could be suitably treated by a general practitioner, and do not require the skill of a specialist. For example, at ophthalmic hospitals a large proportion of the cases are ophthalmia and common diseases of the eyelids; at skin hospitals, pediculi, scabies, and ringworm; at chest hospitals, anæmia and dyspepsia; and so on.

We are of opinion that considerable abuse exists among these special hospitals in the following ways: (1) by the treatment, either free or for a small sum, of patients who could afford to pay a reasonable fee outside; (2) by the admission of patients who do not actually require treatment by a specialist; and (3) by the treatment in some instances of more patients in a given time than can be considered either advisable or defensible.

Recommendations.—In attempting to recommend what course should be adopted by the association as a remedy for the present state of things we are confronted at the outset by a very serious difficulty. The majority of these hospitals would cease to exist were it not for the payments they receive from their patients. A rigid inquiry and the consequent rejection of many patients would so seriously diminish the receipts that some at least of these institutions would be unable to keep open. It is, therefore, *primâ facie* improbable that we shall receive much support in this direction from the hospitals themselves. We recommend that each of these hospitals be asked to appoint an inquiry officer. We recognise the importance of this post being held by a reliable and suitably paid individual. In view of the necessary cost we recommend that hospitals in one locality—or, better still, the hospitals with the same speciality—should combine to support a joint inquiry officer, who shall devote his or her whole time to the work. We recommend that a wage limit be fixed for out-patients, say, 30*s.* a week for a single person and 50*s.* for married people. Some deviation from this rule might be allowed at the discretion of the inquiry officer in cases of a lingering character such as phthisis, or in cases requiring a long course of special treatment. In no instance should an able-bodied person living on his or her private means be admitted as an out-patient to any hospital. We recommend that an appeal be made to the management of the Hospital Saturday Fund asking them to exercise more care in the bestowal of their letters and to exclude as far as possible persons in a position to pay fees. We consider that much might be done if the medical staffs could be induced to take an active interest in the subject of abuse. It is probable no hospital committee would continue to act in opposition to the unanimous views of the staff, provided such views were strongly and persistently laid before them. We therefore recommend that a letter be sent to every member on the staffs of these hospitals asking them to take an interest in this question, and pointing out (*a*) the pauperisation of the patients through the present abuse, (*b*) the serious injury they are doing to their fellow practitioners, and (*c*) the large amount of money they are earning of which they receive nothing.

Subscribers' letters.—We have pointed out that out of the forty-one hospitals ten do not have letters. These do not appear in consequence to suffer any loss in public support, for the average amount of their annual subscriptions is £743, as contrasted with £758, the average annual income from subscriptions returned by the others. At most institutions patients bringing subscribers' letters are admitted unquestioned, and it is certain that large numbers of undeserving cases gain admission in this way. As only six out of the remaining thirty-two hospitals rigidly enforce the use of their letters it is probable that no very serious objection would be raised to the total abolition of the letter system. At any rate, we trace the worst instances of abuse to this system, and we would therefore strongly recommend its total abolition.

Many hospital secretaries have expressed the opinion to

TABULAR STATEMENT OF REPORT OF COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON.

No.	Name of hospital and number of beds.	Subscribers' letters.	Payment by patients.	Inquiry as to patients' means.	Limitation of cases for special treatment.	Limit to number of new out patients.	Patients' payments in 1895.	Annual subscriptions in 1895.	Remarks.
							£	£	
1	Hospital for Skin Diseases, Blackfriars (10 beds).	Out-patients: Yes, about one-quarter. In-patients: Admitted through out-patients.	Out-patients: 1s., 2s. 6d., and 10s. per two months; £490 a year. In-patients: 10s. a week; £59 a year.	Dispenser inquires as to how much a patient can pay.	Limited.	None; average 10.	549	155	There is little or no inquiry into the circumstances of patients. The patients' payments are three and a half times the annual subscriptions.
2	London Skin Hospital, Fitzroy-square (11 beds).	Out-patients: Yes, very few. In-patients: Yes, not enforced.	Out-patients: about 1s. weekly (from 3d. to 2s. 6d.) £636 a year. In-patients: No free beds; 15s. a week; also from £1 1s. to £4 4s. weekly; £204 a year.	The secretary states that he sees all patients and inquires; often rejects one or two a week.	Out-patients: Limited. In-patients: Staff are at liberty to send other cases into private wards.	None; average 3 or 4.	840	122	Questions openly answered by secretary. A fair attempt is made to prevent abuse. The patients' payments are seven times the annual subscriptions.
3	St. John's Hospital for Diseases of the Skin (40 beds).	Out-patients: Yes, the majority. In-patients: Yes.	Out-patients: If no letter, from 1s. to 2s. 6d. weekly, or 10s. a month, privileged cases; £2263 a year. In-patients: 15s. weekly; £105 a year.	All are seen by a clerk, who refers to the secretary doubtful cases, and he frequently rejects.	Limited.	None; average 20 (30—50).	2368	773	The secretary willingly answered questions and appeared to be doing his best to stop abuse according to the views of his committee. The report for 1895 states that £2263 were received from 3857 patients, which gives 11s. 9d. per head. The patients' payments are three times the annual subscriptions.
4	Western Skin Hospital, Great Portland-street (no beds).	Yes, very few; only necessary if unable to pay 1s. or more per week.	Without letter free, or 1s. or 2s. (rarely 10s.) weekly; £144 a year.	The secretary sees and inquires what they can afford to pay; refused two patients in fifteen years.	Limited.	None; average 3.	144	42	Questions freely answered. A patient unable to pay a fee of 1 or 2 guineas would not be considered abusing the charity by paying 10s. The patients' payments are more than three times the annual subscriptions.
5	British Hospital for Diseases of the Skin, Euston-road (12 beds).	Yes; not enforced.	Yes.	None.	—	None.	860	35 and donations	We had the greatest difficulty in obtaining any particulars of this institution. We explained the object of our visits to the officials, who refused us verbal information, and told us to write. When we wrote to the secretary, and afterwards to the members of the staff, we received no reply. When we called again the lady official at the desk refused to send in our card to the member of the staff who was in the hospital at the time. We, however, obtained a report from which we find that patients' payments amount to nearly twenty-five times as much as the annual subscriptions and donations put together.
6	Central London Ophthalmic Hospital, Gray's-inn-road (13 beds).	Out-patients: Yes, about half. In-patients: Yes.	Out-patients: 2d. a visit to 2s. 6d. per month; £426 a year. In-patients: All expected to pay 1s. a day, occasionally £1 a week; £30 a year.	"Inquiry officer" fills in forms, &c., and if he thinks proper brings the patients up to the secretary to be inquired into; has no power himself to question.	Limited.	None; average from 30 to 50.	456	104	Inquiry officer only in name. The report says more than half of the income is derived from patients; four times the annual subscriptions.
7	Royal Eye Hospital, St. George's-circus (40 beds).	Out-patients: Yes, about 1 in 100. In-patients: Admitted through out-patients.	Out-patients: None. In-patients: None. A few at £1 1s. weekly, and four beds at £3 3s. weekly; £318 a year.	The clerk inquires as to the occupation, &c., of out-patients, and occasionally refers to the secretary, who has the right of refusing.	Limited.	None; average 25.	318	344	The secretary was very willing to answer questions, and appeared to be doing her best to prevent abuse.
8	Royal London Ophthalmic Hospital, Moorfields (100 beds).	Out-patients: Yes, about 1 in 20. In-patients: Ditto.	None.	An inquiry officer sees all and refuses more than one a day; the inquiry here even extends to those sent by the Hospital Saturday Fund.	Limited.	None; very large.	318 (boxes)	817	Some care is obviously taken to prevent abuse; the system of inquiry here appears to be good.

Hosted by Google

9	Royal Westminster Ophthalmic Hospital (30 beds).	None.	Out-patients: None. In-patients: None. One bed at £2 2s. weekly; £73 a year.	A clerk sees all and enters occupation, and occasionally refuses.	Limited	None; average 15 to 20.	73	752	The secretary denied the existence of abuse. If the inquiry is thorough it should check serious evil.
10	Western Ophthalmic Hospital, Marylebone-road (12 beds).	Yes, a minority.	Out-patients: No regular payment—an open bowl on secretary's table. In-patients: None.	Assistant secretary sees all and rejects if earning 30s. a week single or 50s. a week married.	Limited.	None; average from 25 to 30.	118 (boxes)	223	No separate heading in accounts for patients' donations, and no register of these is kept. During 1895 1315 cases of ophthalmia were treated; most of these probably did not require a specialist's advice. The report also states that all are admitted without unnecessary formalities.
11	Hospital for Consumption and Diseases of the Chest, Brompton (321 beds).	Rigidly enforced.	None.	Out-patients: Practically none; sister sees all cases and is supposed to refer wealthy patients to the secretary. This is a very rare occurrence; the secretary could not say if it had occurred once during 1896.	Apparently no restriction; the visiting staff has power to see or refuse any case other than chest disease.	None; average from 30 to 40, occasionally 50.	26 (boxes)	7784	Many patients come up from the country. The visiting staff have to attend at noon to enable these privileged people to return to their distant homes the same day. The secretary considered that a patient who persistently gave up a day's work and came from the country and paid from 5s. to 10s. in railway fares was a deserving case for the charity. Practically no inquiry is made; the subscriber who gives the letter is considered responsible.
12	Infirmary for Consumption and Diseases of the Chest and Throat, Margaret-street (no beds).	Rigidly enforced.	None.	None.	Unlimited.	None; average 10.	—	122 and donations	Questions willingly answered.
13	National Hospital for Diseases of the Heart and Paralysis, Soho-square (26 beds).	Out-patients: Yes; about half. In-patients: Yes, with payment.	Out-patients: With letter, free; without 6d. or 1s.; £137 a year. In-patients: All pay; children 5s., and adults from 10s. to £2 2s. weekly; £170 a year.	The secretary inquires and gives special forms to be signed by clergyman or minister in doubtful cases.	All admitted; selection left to staff.	None.	307	958	Questions readily answered; system should be fair if efficiently carried out, but patients come from all parts.
14	North London Hospital for Consumption, Fitzroy-square.	Strictly enforced.	Out-patients: None. In-patients: Occasionally £1 1s. weekly, not encouraged; £38.	Out-patients: None. Seen by clerk; no questions asked; left to subscribers.	Not strictly limited.	None; average 12.	38	1616	No very obvious abuse; the patients all appeared to be poor.
15	Royal Hospital for Diseases of the Chest, City-road (80 beds).	Rigidly enforced.	None.	Out-patients: No inquiry officer; there was one formerly. The visiting staff are at liberty to refer any patient to the secretary. In-patients: None. Subscribers' letters state that patients are without the means of paying for proper medical advice and comforts.	Left to visiting staff.	Yes, 15.	111 (boxes)	2218	Questions very readily discussed by the secretary, who considered less abuse existed than formerly, because the staff were more alive to the fact.
16	Chelsea Hospital for Women (52 beds).	Out-patients: Yes, about three-quarters. In-patients: Yes, rather more.	Out-patients: If no letter, 1s. a week; £263 a year. In-patients: Without letter, 10s. 6d. to £2 2s. weekly; £211 a year.	Out-patients: Clerk inquires and refers doubtful cases to the secretary; this happens daily, and about one-half of these are sent away. In-patients: Some inquiry.	Limited.	None; average from 10 to 25.	474	1635	The secretary answered questions openly and realised the possibility of abuse, and makes a fair attempt to cope with it.
17	The Hospital for Women, Soho-square (60 beds).	Out-patients: None. In-patients: Yes.	Out-patients: None. Contribution box by dispensary; £99. In-patients: Free; 10 beds at £1 1s. a week, £469.	Out-patients: None. In-patients: Have to send a special form signed by a magistrate, clergyman, minister, or medical man.	Out-patients: Sister inquires, and then usually consults visiting staff as to seeing other cases.	Yes, 20.	573	1287	If the in-patient forms are honestly filled up there should be no abuse of this department; as, however, the out-patient department is "perfectly free at 10 o'clock daily, disease and poverty being the only passport required," and no questions are asked. The secretary did not consider there was much abuse. The out-patient sister thought that most patients could quite well pay.

Hosted by Google

TABULAR STATEMENT OF REPORT OF COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON—(*Continued*).

No.	Name of hospital and number of beds.	Subscribers' letters.	Payments by patients.	Inquiry as to patients' means.	Limitation of cases for special treatment.	Limit to number of new out-patients.	Patients' payments in 1895.	Annual subscriptions in 1895.	Remarks.
18	Grosvenor Hospital for Women and Children, Vincent-square (50 beds).	Rigidly enforced.	Out-patients: All pay, from 6*d.* to 1*s.*; £170 a year. In-patients: From 5*s.* to £1 1*s.* weekly; £173 a year.	Out-patients: None with letters. Some inquiry if without.	Not limited to gynæcological cases.	None: average from 10 to 15.	£ 344	£ 504	The patients are seen by the lady visitors, who fill in letters as to name, &c. Spaces in letters for rent and means of livelihood are left blank; no questions are asked. The hospital is being rebuilt.
19	Royal Hospital for Children and Women, Waterloo-road (52 beds).	Rigidly enforced.	Out-patients: 1*d.*, £127 a year. In-patients: From 1*s.* a week, £132 a year.	Out-patients: Sister inquires and refers to the secretary or medical officer, who refuses if thought necessary, which seldom happens. In-patients: Not admitted without a medical man's certificate.	Limited.	None; average 25, occasionally 50.	259	793	The secretary thought that abuse existed in all out-patient departments. We consider under the circumstances that so few patients are sent away that abuse exists.
20	Samaritan Free Hospital for Women and Children (53 beds).	None.	None.	Out-patients: Children, none; adults, space on letters for rent and means of livelihood. (We do not know if these are filled in.) In-patients: Fairly full particulars are requested.	—	None.	8 (boxes)	1615	The secretary was very polite, but did not wish to answer questions without the special consent of his committee. We were unable to ascertain that any real inquiry was made.
21	Central London Throat, Nose, and Ear Hospital, Gray's-inn-road (17 beds).	None.	Out-patients: 6*d.*, 1*s.*, and 2*s.* 6*d*; £1136 a year. In-patients: Majority free; 14*s.* weekly; £176 a year.	The secretary sees all and fills in forms, rejecting about fifty a year.	Limited.	None; average 25.	1322	318	Questions were openly answered and every facility for inquiry offered. The secretary did not think as much abuse existed as formerly and appeared very anxious to avoid it. About one-seventh of the patients are recommended by medical men, and many come from a distance. The payments from patients amount to four times the annual subscriptions.
22	Hospital for Diseases of the Throat, Golden-square (26 beds).	Out-patients: Yes, about one-eighth. In-patients: Rather less.	Out-patients: With letter free; without from 1*s.* to 2*s.* 6*d.* weekly; £2486. In-patients: With letter free or payment of 10*s.* weekly, 2*s.* 6*d.* to 25*s.* weekly; £372 a year.	Out-patients: The clerk inquires and refers to secretary; a daily occurrence. In-patients: Secretary sees.	Limited to throat, nose, and ear, including enlarged glands, goitre, &c.	None; average from 30 to 40.	2858 (In 1894)	286 (In 1894)	It appears the question here asked is whether a patient can afford a specialist's fee of from one to two guineas a visit. The patients' payments are nearly ten times the amount of the annual subscriptions.
23	London Throat Hospital, Great Portland-street (5 beds).	Out-patients: Yes, about one-third. In-patients: Admitted through out-patients.	Out-patients: With letter free; without, expected to pay from 1*s.* to 2*s.* 6*d.* weekly. In-patients: About 5*s.* weekly; £737 a year.	Left to visiting staff.	Limited.	None; average 20.	737	118	A proper system of inquiry is absent. The patients' payments are six times the amount of the annual subscriptions.
24	Metropolitan Ear, Throat, and Nose Hospital, Fitzroy-square (no beds).	Yes, about one-eighth.	From 2*s.* to 5*s.* per visit, occasionally £1; £101 a year.	None.	Left to the visiting medical officer.	None.	101	11	There was considerable hesitation on the part of the secretary in replying to questions. The medical officers are allowed to see private patients at the hospital. We were unable to ascertain who decided which were private and which were hospital cases. Many come from the country and can have their medicine repeated by post. The subscribers' letters apparently exist to gratify the Hospital Saturday Fund. The patients' payments amount to ten times the sum of the annual subscriptions.
25	Royal Ear Hospital, Frith-street, Soho (9 beds).	Out-patients: Yes, about a quarter. In-patients: A few.	Out-patients: 1*s.* per visit; £468 a year. In-patients: From 5*s.* to 12*s.* weekly; £127 a year.	Lady secretary inquires, and refuses unsuitable cases.	Limited.	None; average 15.	595	79	We saw no evidence of any very great abuse, but patients' payments amount to nearly eight times the sum of the annual subscriptions.

Hosted by Google

26	Municipal Throat and Ear Infirmary, City-road (no beds).	—	—	—	—	—	280	—	No report is published. This appears to be a private concern, and, we presume, patients pay the medical officer.
27	Hospital for Epilepsy and Paralysis, Regent's Park (25 beds).	Out-patients: Yes, if unable to pay 6d.; about one-half have letters.	Out patients: With letter, free; without, pay from 6d. to 2s. 6d. weekly; £226 a year. In-patients: About half pay from 5s. to 10s. weekly; private wards from £1 11s. 6d. to £3 3s. weekly; £406 a year.	Out-patients: Dispenser sees and questions, and occasionally refers to secretary.	Out-patients: left to visiting staff. In 1895, 41 cases other than nervous were treated. In-patients limited.	None; average from 2 to 3.	632	380	The secretary was very courteous and quite alive to the possibility of abuse, but could not suggest any improvement except an inquiry officer or reference of all metropolitan cases to the Charity Organisation Society. The patients' payments are considerably more than the annual subscriptions.
28	National Hospital for the Paralysed and Epileptic, Queen-square (130 beds).	Out-patients: Yes; less than one-half. In-patients: None; many admitted through out-patients.	Out-patients: None. In-patients: Free, or £1 1s. weekly (32 beds); also private wards, from £3 3s. to £5 5s. weekly; £1799 a year.	Out-patients seen by steward, who possibly refers to the secretary; this may happen once or twice a month. In-patients have to get letter signed of inability to pay for adequate medical treatment.	Limited; registrar selects.	None; average 15 (from 10 to 35).	1799	1761	Information not readily given. The secretary considered his institution differed from all others and was not a public body, and no one had any right to interfere with it. More money is received from the in-patients alone than in annual subscriptions.
29	West-end Hospital for Diseases of the Nervous System and Paralysis, Welbeck-street (50 beds).	Out-patients: Yes; about one-half. In-patients: Yes; if free.	Out-patients: With letter, free; without, from 1s. to 5s. weekly; £354 a year. In-patients: With letter, free; without, from 3s. 6d. to £1 weekly; £120 a year.	The secretary sees all patients and questions as to means; often rejects two a week; he never questions those with Hospital Saturday Fund or Hospital Sunday Fund letters.	Left to visiting staff.	None; average 7 or 8, occasionally 20.	474	800	There is a good attempt at inquiry, and with the exception of those with Hospital Saturday Fund and Hospital Sunday Fund letters, abuse to any extent can only exist through deceit.
30	British Hospital for Mental Diseases and Brain Disorders, Euston-road (no beds).	A few bring letters; all have to get them.	None.	The secretary sees all and makes inquiries, and in doubtful cases tells patients to bring a letter from a clergyman stating poverty, &c.	? Limited.	None; average from 6 to 8.	—	—	No report had been issued since 1894.
31	City Orthopædic Hospital, Hatton Garden (50 beds)	None.	Out-patients whose wages are over £2 are expected to put 2s. 6d. in the box for two months. In-patients: Free, and six beds at £1 1s. weekly; £6 6s.	The secretary sees all cases and fills in letters with occupation and income; if he has any doubt he refers case to the Charity Organisation Society (about five or six a year).	Limited.	None; average 6.	19	416	The secretary appeared willing to give all information. We should have considered it hardly worth the secretary's time to note the very small amount represented as received from patients.
32	National Orthopædic Hospital, Great Portland-street (60 beds).	Out-patients: Yes; but very few are brought. In-patients: Yes.	Out-patients: None. In-patients: 7s. 6d. under twelve years of age, and 10s. 6d. over twelve weekly; £101 a year.	Out-patients: Matron sees personally all cases and makes inquiries; refuses herself or refers to the secretary.	Limited.	None; average from 6 to 10.	1001	349	Questions very openly answered. Apparently every precaution to prevent abuse is taken, the possibility of which is most fully recognised.
33	Royal Orthopædic Hospital, Oxford-street (50 beds).	Out-patients: Yes, majority bring or have them given. In-patients: Yes, not enforced.	Out-patients: None; £16 in boxes. In-patients: Free or pay from 2s 6d. to 10s. weekly; £107 a year.	Out-patients registered by porter, seen by surgeon, who can refer to secretary, who refuses about one a month.	Limited.	None; average 2 or 3.	123	540	Questions very openly answered. The secretary has put in letters that "Patients may be called upon to furnish such information as will enable the authorities to judge of their eligibility for charitable relief."

TABULAR STATEMENT OF REPORT OF COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON—*(Continued)*.

No.	Name of hospital and number of beds.	Subscribers' letters.	Payments by patients.	Inquiry as to patients' means.	Limitation of cases for special treatment.	Limit to number of new out-patients.	Patients' payments in 1895.	Annual subscriptions in 1895.	Remarks.
							£	£	
34	St. Peter's Hospital for Stone and Urino-genital Organs, Covent-garden (26 beds).	Out-patients: Yes, very few. In-patients: None; admitted through out-patients.	Out-patients: With letters, free; without, 6*d*., 1*s*., or 10*s*.; £1947 a year. In-patients free; £254; two beds at £5 5*s*. a week, £185 a year.	Out-patients: Secretary sees and questions, and possibly refuses fifty a year.	Left to surgeon.	None; average 12.	2186	250	Questions freely answered. Nearly £2200 a year received from patients, more than three times the annual subscriptions and donations together; probably much abused.
35	Gordon Hospital for Fistula, Piles, and Diseases of the Rectum (20 beds).	No regular subscribers' letters.	Out-patients: Free; box, £68 a year. In-patients: Nearly all pay from 2*s*. to £3 3*s*. weekly; £759 a year.	Out-patients: None; left to visiting staff. In-patients inquired very fully into by secretary, who refuses about two a year, and keeps a very complete detailed record.	Left to surgeon.	None; small.	827	143	Questions most openly answered and fullest facilities for inquiry given. We doubt if there is much abuse with the in-patients; as, however, there is no inquiry with the out-patients there appears to be considerable abuse of this department. The patients' payments are nearly six times the annual subscriptions.
36	St. Mark's Hospital for Fistula, City-road (34 beds).	None.	Out-patients: None; boxes, £42 a year. In-patients: None.	Practically none.	Hospital surgeon selects.	None; average 12.	42 (boxes)	306	In the absence of any genuine inquiry abuse must exist, probably to a considerable extent.
37	Lock Hospital and Rescue Home (135 beds).	None.	Out-patients: Pay 2*d*., 6*d*., 1*s*. up to 5*s*. per visit; £1422 a year. In-patients: None.	Out-patients: The secretary, clerk, or dispenser inquires, and has the right of refusing. In-patients: No inquiry; usually recommended by clergymen or medical men.	Strictly limited.	None.	1422	75	We could get no direct evidence of abuse by the out-patients; but it probably exists. The majority of in-patients come from all parts of the country without any inquiry, so it is difficult to believe that no abuse exists. The out-patients' payments are over eighteen times the annual subscriptions.
38	Dental Hospital of London, Leicester-square (no beds).	Yes.	None; have to pay for extra gold for stopping; £239 a year.	None.	Limited.	None.	305	1121	There is an appliance department where very strict inquiry is made and no abuse exists, but, as all subscribers' tickets are admitted without inquiry, abuse must exist, especially as a large school is attached, and students naturally prefer clean to dirty people.
39	National Dental Hospital, Great Portland-street (no beds).	Yes; the majority.	With letter, free; without, free or pay 2*s*. 6*d*. for gas or gold stopping; £1113 a year.	Porter sees all, and has power to refuse. This occasionally happens. No inquiry of those with letters.	Limited.	None; often from 70 to 100.	1113	126	The inquiry does not appear very efficient; only the wealthy classes refused, if found out. Hospital practically self-supporting. Notices to the effect that the hospital is only for the necessitous poor are put up. Patients' payments are eight times the annual subscriptions.
40	Friedenheim, or Home for the Dying (40 beds).	None.	In-patients: Most free or pay from 2*s* 6*d*. to 10*s*. weekly; occasionally £1 1*s*.; £308 a year.	Certificate by attending medical man has to be sent in.	Cases have lived four years.	—	308	511	No evidence of abuse.
41	Cancer Hospital, Fulham (105 beds).	None.	None.	—		—		1994	The secretary refused to be interviewed and also to answer our questions when sent by post. We have no particulars of out-patients. Cases other than cancer are treated as in-patients in large numbers, such as piles, fistulæ, tuberculosis, syphilis, abscess, &c. In fact, according to the report, only rather more than half the patients are acknowledged to be suffering from diseases of a cancerous nature We consider it unfortunate that an institution which appeals to the public as a cancer hospital and receives, we believe, donations and legacies for this reason should treat other conditions.

us that the amount of the specialist's fee for private consultation often conduces to instances of abuse of the special hospitals. Thus numbers of patients who pay the hospitals as much as from 5*s*. to 10*s*. are unable to pay 1 or 2 guineas to the medical man at his own house. With reference to this we fail to see any very strong objection to institutions acknowledged to be on a business and not on a charitable basis. In such institutions patients *bringing an introduction from their general practitioner* (this we regard as essential) might obtain a specialist's advice on the payment of a small sum, say, from 5*s*. to 10*s*., a portion of which would go to the specialist himself.—We are, Gentlemen, your obedient servants,

W. KNOWSLEY SIBLEY, M.D. Cantab., M.R.C.P. Lond.,
ERNEST A. SNAPE, M.D. Brux., L.R.C.P. Lond.

HISTORICAL NOTES ON MEDICINE, SURGERY, AND QUACKERY.

III.[1]

SOME time between 1780 and 1785 an extraordinary exhibition took place in a garden in the upper part of Fleet-street, Liverpool, when that street, though laid out, was not a thoroughfare. A person professing to be a medical practitioner, called Dr. Graham, arrived in the town and recommended the use of earth baths as a cure for various complaints. His plan was to have the patient buried up to the neck in earth, and in order to set the example he and a woman who was said to be his wife were buried up to their necks in the garden with their faces towards each other. They had their heads dressed with hair powder, as was the fashion at that period, and the public were admitted on payment of a small sum. There is not any reason, however, to believe that they induced any patient to follow their example.

The following advertisement appeared in Williamson's *Liverpool Advertiser* of Feb. 18th, 1757: "To prevent the Unwary from being drawn in by ignorant Pretenders to Midwifery in this town (as I have been lately), I think it my duty to acquaint the public that my late beloved wife, Mary Reily, was taken suddenly in labour on Saturday, the 5th instant, upon which the Surgeon we had formerly on the like occasion employed was sent for, but not then being at home, were under the Necessity of immediately applying to some other. Mr. John Wareing, a young Surgeon in Preeson's-row (unfortunately for me), was the person brought, who pretended to be acquainted with such like cases, & took upon him the remainder of the business of a Midwife (the child being born before his arrival); and tho' Contrary to the advice of an experienced Woman Midwife, who was called in, in the Hurry, & told him he was doing wrong, has occasioned (thro' ignorance) the Loss of my dear Wife and Child, who are since dead. This I am ready to attest upon oath, & can bring several experienced Persons to verify.—THOMAS REILY, Hatter, in Redcross-street." Something of the proverbial madness which clings to the calling of a hatter must have moved Mr. Reily in this affair. In the next number but one of the paper appeared a reply couched as follows: "Whereas an Advertisement was inserted in this paper of the 18th ult., signed by one Thomas Reily, a Hatter, in Redcross-street, addressed to the public, greatly aspersing the Character of Mr. John Wareing, a Surgeon, in Preeson's-row, in Liverpool, thereby charging him with being the instrument, thro' Ignorance, of the Death of said Reily's Wife and Child; which upon strict Enquiry is found to be altogether unjust and untrue; as it will be proved such Advertisement was inserted therein at the Instigation and by the Dictating of a Person in Town whose Character is too well known to want an Eclaircissement; and can assure the public that such Advertisement is utterly false and scandalous, and without the least Foundation, and was intended, thro' Malice, to injure the Character of Mr. Wareing, and no other Motive; as Mrs. Reily for many months before laboured under a Consumption; the Birth untimely, being but in the seventh [? month] of pregnancy, and the Child born before Mr. Wareing was sent for, and she was attended by another Surgeon (whose Prescriptions only she took) both before such Delivery and afterwards, till the Time of her Death, which was on the 10th Day after her Delivery, and not before; for which an Action at Law is, or soon will be, brought against the Writer and Composer of the same.—N.B The publisher of this Paper assures the Public that the Advertisement inserted in the *Manchester Advertiser* of last Tuesday, relative to the above affair, is entirely False, notwithstanding what is there asserted, and the same was refused on that Account to be inserted in our last Paper."

On July 29th, 1757, the following announcement (for which the printer received 12*s*., according to the file copy) appeared in the *Advertiser*: "To the Public: Whereas an Advertisement was inserted on Friday, the 18th of February, 1757, in this paper, Signed by me the underwritten Thomas Reily, a Hatter in Redcross-street in Liverpool, adressed (as therein is mentioned) to the public, *to prevent the Unwary from being drawn in by ignorant Pretenders to Midwifery*, whereby the Character and Reputation of Mr. John Wareing, Surgeon, in Preeson's-row, Liverpool, is greatly aspersed and injured by attributing the Death of my late Wife, Mary Reily, and the Child which she had then lately been delivered of, to the Ignorance of said Mr. Wareing in the Practice of Surgery and Midwifery; to which false and scandalous Aspersion, I, the said Thomas Reily, was irritated by Mr. Ralph Holt, of Liverpool, Surgeon, the person to whom Mr. Wareing faithfully served a legal apprenticeship; and for which Injury Mr. Wareing has had Recourse to the Law against me and Mr. Holt for Satisfaction, but upon a Meeting of Mr. Wareing, Mr. Holt, and myself (at the Request of Mr. Holt), I find that Mr. Wareing did faithfully perform his Duty to my said late Wife, and that such Aspersion and the whole of the said Advertisement is utterly false, and was intended to injure the Character Mr. Wareing, for which I am extremely sorry and sincerely ask his Pardon. And I the underwritten Ralph Holt, of Liverpool, Surgeon, do hereby declare that the said Mr. Wareing did faithfully perform his Duty as Man Midwife to Mrs. Reily, that the whole Contents of this Advertisement are strictly true, and that the said Advertisement of the 18th of Feby. last is without the least Foundation; that said Mr. Wareing faithfully served me a legal Apprenticeship in the Practice of Surgery and Midwifery, and after that studied the same and was regularly educated therein at one of the best Schools in Great Britain, and that I believe the said Mr. Wareing to be in every Respect duly qualified in these Professions; and am sorry that I was in any wise the Occasion of so false and scandalous an Aspersion, as I was misinformed relating to the subject matter of the said Advertisement, for which I have not only payed all Cost & Charges incurr'd by the said Prosecution commenced against me & the said Thomas Reily, but have asked Pardon of the said Mr Wareing in Public. Witness our Hands the 27th of July, 1757.—THOMAS REILY, Hatter; RA. HOLT, Surgeon." Even at this distance of time one cannot but rejoice at the failure of this dastardly attempt to ruin the young surgeon on the very threshold of his career.

In consequence of the ravages of the small-pox it was resolved, in the month of March, 1783, that a general inoculation of the inhabitants of Liverpool should take place. The following medical men were formed into an Inoculation Society for that purpose: Dr. Houlston, Dr. Brandreth, Dr. Binns, Dr. Worthington, Dr Camplin, Dr. Currie, Dr. Lyon, Mr. Alanson, Mr. Blundell, Mr. Buddicumb, Mr. R. Gerard, Mr. J. Gerard, Mr. Goldie, Mr. Hughes, Mr. Moss, Mr. Parke, Mr. Renwick, Mr. Shortcliffe, and Mr. Tetlow.

Dr. Currie, the biographer of Burns, was born on May 31st, 1756, at Kirkpatrick Fleming, near Gretna, his father being the parish minister. He settled in Liverpool as a physician in 1780, and filled for twenty-five years a most honourable position. Dr. Currie published, under the pseudonym of "Jasper Wilson," a letter to Mr. Pitt strongly condemnatory of the war with France, which caused an extraordinary sensation. Three large editions were sold in two months, besides reprints in Scotland, Ireland, and in the country. It was reprinted in America and translated into French and German. Dr. Currie died on Aug. 31st, 1805. His life was published by his son, William Wallace Currie, the first Mayor of Liverpool under the Reform Act. Dr. Currie was a staunch opponent of the slave trade. In 1788 he wrote: "The general discussion of the slavery of the

[1] Nos. I. and II. were published in THE LANCET of March 6th and March 27th, 1897, respectively.

Hosted by Google

negroes has produced much unhappiness in Liverpool. Men are awaking to their situation, and the struggle between interest and humanity has made great havoc in the happiness of many families. If I were to attempt to tell you the history of my own transactions in this business, I should consume more time than I can spare. Altogether I have felt myself more interested and less happy than is suited to my other avocations. The attempts that are continually made to justify this gross violation of the principles of justice one cannot help repelling; and at the same time it is dreadful to hold an argument where if your opponent is convinced he must be made miserable. A little scoundrel—a Spanish Jesuit—has advanced to the assistance of the slave merchants, and has published a vindication of this traffic from the Old Testament. His work is extolled as a prodigy by these Judges of Compositions and is, in truth, no bad specimen of his talents, though egregiously false and sophistical, as all justifications of slavery must be. I have prompted a clergyman—a friend of mine—to answer him by telling him that if such be religion I would 'none on 't.' Whatever be the issue of the present efforts for the Parliamentary abolition of the slave trade, much good, I am persuaded, will be done by the discussion of the subject. We shall in future find fewer persons so abandoned in their modes of reasoning and practice towards the unhappy negroes as many now are, for there is something in the censure of man which the greatest villain dreads and does much to avoid. It likewise gives one a better opinion of the present generation to find that they can be roused by the pure dictates of humanity, independent of all party questions or distinctions, and there can be no doubt that sooner or later the voice of freedom and truth will exert itself on this subject with irresistible influence. Priestley, who spent an evening with me lately, is of opinion that no effort, even of the humblest individual, is ever lost. Let there be but agitation of any question and the interests of truth and virtue are promoted; no matter in what direction the motion comes, let there *be* motion—that is enough; the tide-mill goes equally whether the water runs with the flood or the ebb. This is a great man, and a most agreeable one." By writing in defence of the negro and in reprobation of the slave trade Dr. Currie, then rising into notice in Liverpool as a physician, had the courage to risk popularity and practice. To his own imperishable honour and to the honour of the great profession to which he belonged, his name stands in the page of history as one of the few men "who first raised the standard of justice and truth in Liverpool against a profitable traffic which had been sanctioned for centuries by the practice of every European nation, which had been recognised in numerous national treaties, and which did not want defenders even among t the ministers of religion themselves." Dr. Currie raised his voice against the pernicious practice which had been introduced in the new streets on the south side of the town of building houses to be let to labourers in small confined courts which had a communication with the street by a narrow aperture, but no passage for air through them. The consequences of overcrowding, filth, want of light, &c., were already frightful in the town. Fever naturally took up its abode among the dark dens where the ashpits sent their liquid filth oozing through the walls and their pestiferous gases flowing into the windows of the densely packed houses. In 1788 the physicians of the town brought this fearful state of things under the notice of the Mayor and magistrates, and in 1802 the corporation applied to Parliament for an Improvement Bill, wisely seeking in framing it information and suggestions from the medical officers of the infirmary and dispensary. An interesting report, containing enlightened views on sanitary matters, was drawn up by Dr. Currie and his coadjutors, and on this the sanitary clauses of the Bill were based. But the interests of different individuals being affected by the Bill, the old cry of rights of property was, as usual, raised in defence of the wrongs of property, and inferior consideration triumphed over the public good. The attempt to remove the causes of the evil failed; but at a cost of 9*d.* in the pound, which if properly expended would have gone far to remedy the mischief, a fever hospital was erected to mitigate the scourge, and a new cemetery was bought to hide its victims. These facts were stated by Mr. James Newlands, F.R.S.S.A., Borough Engineer of Liverpool, before a meeting of the National Association for the Promotion of Social Science, Department of Public Health, held at St. George's Hall on Oct. 15th, 1858. "I beg to claim your attention to the Report that these gentlemen made," said Mr. Newlands, referring to the report of Dr. Currie and his professional brethren; "the clear perception of sanitary principles which they possessed and unfolded in this document would do honour to any man in the present day."

In January, 1847, Dr. Duncan was appointed medical officer of health for Liverpool, an office in which he rendered the greatest services to the health of the town. At the time of this appointment Mr. Edwin Chadwick, the Registrar-General, made the following remarks on the necessity of a liberal expenditure for sanitary purposes in a place at once so rich and so unhealthy as Liverpool then was: "A parsimony," he said, "for objects of such importance as the saving of pain and misery would ill become Liverpool, where there is in course of expenditure for splendour on one single edifice, St. George's Hall, upwards of £100,000—a sum which would, if so applied, serve to sweep and cleanse in perpetuity and make decent the filthy by-streets of upwards of 23,000 houses out of the 45,000 houses which are under the corporation jurisdiction. And allow me to pause by the way," he added, "to offer the suggestion for consideration, since that edifice is to be adorned with statues, whether a place may not be found for one, amongst other men who have adorned Liverpool, to the late Dr. Currie, who, with the physicians of the fever hospital, in the year 1802, pointed out preventive measures which if they had been adopted would have prevented Liverpool being now the least healthy city in Great Britain, and would have averted the heavy mortality burdens by which its population is now depressed." Commenting on this Mr. Thomas Baines, in his History of Liverpool, remarks: "The suggestion of ornamenting St. George's Hall with a statue of a man whose memory is so justly dear to the friends of literature, freedom, and benevolence as that of Dr. Currie must ever be is worthy of adoption; but it must be added, in justice to Liverpool, that whilst nearly £200,000 has been expended in adorning the town with one of the noblest buildings of modern times, two, if not three, times that sum has been spent, or is spending, on improvements designed to promote the public health by means of sewage and cleansing, of baths and washhouses, of improvements in the residences of the poorer classes, and of an abundant supply of water, brought from a distance of many miles. It is doubtful whether a town like Liverpool, which can be reached at a trifling expense by the most destitute of the Irish poor, will ever be as healthy as towns less accessible to that poverty-stricken people; but it would be a great injustice to suppose that the people of Liverpool are erecting magnificent buildings and leaving the poor to perish. Nothing can be further from the truth." Mr. Baines was writing of a period when all Ireland was suffering under the plague of famine, when the influx of the destitute into Liverpool was so overwhelming that not less than 29,417 persons received parish relief, as casual poor, in six days, in addition to the resident poor. The actual number of Irish poor who arrived in the town from Jan. 16th to April 17th in 1847 was 127,785 persons—namely, 69,695 men, 36,234 women, and 22,686 children.

"Liverpool a Few Years Since," by "An Old Stager" (the late Rev. James Aspinall, M.A., Rector of Althorpe), a book published in 1852, mentions several medical men of note. "Dr. Currie, so celebrated in his day and so celebrated yet, lived in Basnett-street. Bold-street had its Tobins, Aspinalls, Dawsons, &c. That kind-hearted man, Rector Renshaw, lived here in a corner house, with its door opening up Newington Bridge. ..... Opposite to the house of Rector Renshaw was that of Harry Park, as we familiarly called him, the Abernethy or Astley Cooper of Liverpool, as a surgeon, we believe, second to no man of his day. At the very next door lived Dr. Brandreth, of whose eminence, or pre-eminence, as a physician it is impossible to speak too highly. In all our wanderings over and sojournings in different parts of the world we never remember to have met with a medical man whose standing was so thoroughly ascertained, admitted, and appreciated. And his position was as elevated in the social as in the medical world. There was no appeal against the fiats which Fashion issued from her seat in Bold-street. ..... In Seel-street was Mr. Perry, the first dentist of his day and locality; and next door to him lived the tremendous Mrs. Oates, the best instructress of small children in the rudiments of English whom the world has ever seen. She had a knack of measuring baby capacity and of drawing out all that it contained, helped thereto doubtless by a concentrated essence of birch-rod look which she constantly wore in school hours,

Hosted by Google

and which had "no mistake" written upon it in large letters."

Besides the illustrious Roscoe, who in 1789 was elected President of the Liverpool Library, there were associated with him as active members of the committee, amongst others, Dr. Currie, Dr. Bostock, Dr. Rutter, and Dr. Worthington. Of Dr. Currie we have already spoken. John Bostock, M.D., was the author of an "Essay on Respiration," 8vo, Liverpool, 1804; "Remarks on the Nomenclature of the New London Pharmacopœia," read before the Liverpool Medical Society, 1810; "Elements and System of Physiology," 8vo, 1824; and numerous communications to the *Medical Memoirs* and *Nicholson's Journal*.

Dr. Rutter, a celebrated physician of his day, resided in St. Anne-street, then the fashionable quarter of the town. He was of the Society of Friends, like Dr. Jonathan Binns. Dr. Rutter was the founder of the Medical Institution and Library in Hope-street, the books of which were bequeathed by him to the profession. The Liverpool Athenæum Newsroom was also established by Dr. Rutter in the year 1798, associated with him being Mr. Joshua Lace, Mr. Roscoe, and Mr. Currie. The idea of the Athenæum arose from the annoyances that gentlemen had to encounter at the "Merchants' Coffee House" in the Old Churchyard, and at "Pontack's" in Water-street, through the boisterous conduct of the sea captains who frequented those taverns. The newsroom stands on the site of a large pond whereon the lads used to slide in winter. In 1788 the dispensary was erected on the site of an orchard adjoining the pond. This charity owed its existence to Mr. Wyke, a watchmaker in Dale-street, who in 1778 started it at No. 75, Prince's-street, John-street. On the sale of the property in Church-street in 1829 for £6000 the dispensary was removed to Vauxhall-road. Towards its original foundation the subscriptions of 102 subscribers, amounting to £117 12*s.*, were supplemented by 100 guineas contributed by the parish. According to the report of the dispensary published at the beginning of the year 1786 it appeared that 66,359 persons had been relieved up to that time. The subscription list and the list of the medical officers of this charity for the first year of its institution gives us practically a register of the leading members of the profession at that time practising in Liverpool. Its physicians were Dr. Joseph Brandreth, Dr. Jonathan Binns, and Dr. James Worthington; its surgeons were Mr. Wright Gleave, Mr. Edward Alanson, and Mr. James Gerard. These gentlemen subscribed a guinea each, as also did Dr. W. F. Blencome, Dr. Joseph Camplin, Dr. Matthew Dobson, Dr. Thomas Houlston, Dr. John Kenion, Dr. Wainwright, Dr. Henry Richmond, and the following surgeons: Robert Buddicombe, Henry Parke, John Lyon, Richard Gerard, William Moss; and James Leigh, apothecary. Among the non-professional subscribers were the illustrious Roscoe and Benedict Paul Wagner, merchant, the latter being the maternal grandfather of Felicia Dorothea Hemans. The rent of the institution for one year is put down at £3, and the salary of Mr. Avison, the apothecary, at £60.

Appended are a few facts concerning the above-named physicians and surgeons, taking them at random. Dr. James Worthington resided in Drury-lane, off Water-street, where also lived the wealthy merchant and ex-slave captain William Boates, who on being told that one of his ships had captured a rich prize ran about the pier-head exclaiming, "Billy Boates, once a beggar, now a lord." Billy had been a waif found in a boat. Dr. Worthington published a treatise on the "Mineral Spring in the Quarries near St. James's Mount." Mr. William Moss, surgeon to the Liverpool Lying-in Charity, published "An Essay on the Management, Nursing, and Diseases of Children," 1794; also a "Medical Survey of Liverpool," 1794. Jonathan Binns, M.D., was for many years senior physician to the Liverpool Dispensary. He published at Edinburgh, in 1762, "Dissertatio Medica in Auguralis de Exercitatione." He superintended for some time the school belonging to the Society of Friends in Yorkshire, and whilst there published an English Grammar and also a Vocabulary. He removed to Lancaster, where he practised as a physician until the time of his death in 1812, aged sixty-five years. Dr. Binns had the courage to oppose the slave trade when it was bringing a profit of from £200,000 to £300,000 a year into the port of Liverpool. The only two Liverpool members whose names appear in the list of the original members of the Society for the Suppression of the Slave Trade were Dr. Jonathan Binns and William Rathbone. Liverpool has never lacked a William Rathbone since to help in all good work, and it was the lot of Sir Joseph (now Lord) Lister, on Sept. 20th, to pay a graceful tribute to the munificence of the present William Rathbone in connexion with the efficient nursing of pauper patients in the Workhouse Infirmary.

Mr. Richard Gerard, surgeon, Mayor of Liverpool in 1780, resided at one time in Church-street, and at another period in Duke-street. He was the father of Dr. Gerard, and an especial pet with the ladies in St. Anne-street because he accepted all their invitations to their routs, which must have been a trying ordeal. Dr. Gerard's famous recipe for making toffee has rendered Everton as well known in connexion with it as Shrewsbury by its cakes, Bologna by its sausages, Strasburg by its pies, Chelsea by its buns, and Islay by its whisky. The original possessor of Dr. Gerard's recipe was one Mistress Molly Bushell, who resided in one of the old cottages (about midway up "the town" of Everton) which were said to have been the quarters of the Royalist officers when fiery Rupert besieged Liverpool. Toffee was recommended at first as a specific for coughs, colds, and catarrhs, and it so speedily became known and patronised by the sweet-consuming world that it tended greatly to Molly's mental content and worldly prosperity.

Matthew Dobson, M.D., F.R.S., was the son of the Rev. Joshua Dobson, "a respectable Dissenting minister" in Yorkshire, and was originally designed for the ministry. His inclinations, however, led him to the study of medicine and he took his degree at Edinburgh. He afterwards settled at Liverpool, and acquired very considerable practice; but bad health induced him to remove to Bath, where he died in the year 1784, and was buried at Walcot Church. At the time of his death he was preparing materials for the natural and medical history of the town of Liverpool. In Enfield's History are two essays by him: Observations on the Temperature of the Air, and on the Variations in the Temperature of the Sea. He also published the following: "A Medical Commentary on Fixed Air," London, 1779; "Experiments and Observations on the Diabetes"; "A Successful Treatment of a Supposed Hydrophobous Internus" ("Medical Observations and Inquiries," vol. vi., p. 48); "On the Benefit of a Resuscitated Salivation in the Cure of Several Anomalous Symptoms" (Ibid., p. 174); "A Description of a Petrified Stratum formed from the Waters of Matlock in Derbyshire" (Philosophical Transactions, Abstract, 13, p. 510, 1774); "Experiments in a Heated Room in the Hospital at Liverpool" (Ibid., p. 687, 1775); Observations on the Annual Evaporation at Liverpool (Ibid., 14, p. 137, 1777); and "An Account of the Harmuttan, a Singular African Wind" (Ibid., 15, p. 23, 1781). Dr. Dobson was succeeded in his practice by Dr. Brandreth from Ormskirk. Whilst resident in Liverpool he lost a daughter, to whose memory a monument, with an affectionate Latin inscription, is placed in the chapel near the Dingle. Mrs. Susannah Dobson, formerly Miss Dawson of the South of England, the wife of Dr. Dobson, was renowned in her day as the author of the "Life of Petrarch," abridged from the French, 2 vols, 8vo, London, 1775; "The Literary History of the Troubadours," collected and abridged from the French of De St. Pelaie, London, 1779; "Memoirs of Ancient Chivalry," London; "Petrarch's View of Human Life," 1791; and "A Dialogue on Friendship and Society" (anonymous). She died in London in 1795, and was buried at St. Paul's, Covent-garden. William Lowndes, grandson of Dr. Dobson, was the author of a "Treatise on the Law of Legacies."

Mr. Edward Alanson was the author of "Observations on Amputation," 8vo, 1779; second edition, 1782; "An Account of Simple Fracture of the Tibia" (Medical Observations, vol. iv.). Dr. Houlston was a physician of some note in his day. He discovered in 1773 a ferruginous spring of water in the great quarry, which he dignified by the title of the "Liverpool Spa." The great quarry is now St. James's Cemetery, which is overlooked by Hope-street. This spot in Dr. Houlston's time was covered with the wild heather and furze, while the spring now flowing in the cemetery is not that about which Dr. Houlston wrote, although it has been credited with the same properties, tending to the cure of rheumatic complaints. Dr. Houlston had a house in Chapel-street, probably at the junction of that street with High-street, as, according to one authority, he resided in the latter thoroughfare, which then extended to Chapel-street. To-day the Liverpool Town Hall flanks one side of all that remains of High-street, and the merchants of Liverpool on 'Change make and lose fortunes

Hosted by Google

on the spot where the old-world physician wrote his prescriptions and healed the men and women whose thoughts were engrossed by the prices of slaves and sugars. Dr. Houlston took a great interest in the public institutions of the town, and he was the originator of the Humane Society. An essay entitled "Plain Directions for the Recovery of Drowned Persons," signed by "Humanus," written, there is reason to believe, by Dr. Houlston, appeared in the *Liverpool Journal*, Sept. 24th, 1773, but no proceedings were then taken to form a society. The Humane Society in London was instituted in 1774 at the suggestion of Mr. Hawes and Dr. Cogan. The latter had, in 1773, translated a Dutch memoir on the subject, and in 1775 a house of reception was opened in Liverpool, on the north side of the old dock (the site of the Custom House), and an institution established at the instance of Dr. Houlston on a similar plan to that in the metropolis, which was maintained with vigour for some years, but was afterwards suffered to fall to decay. A new society, entitled the Marine Humane Society, was established in 1823. Dr. Houlston published the following: "An Essay on the Liverpool Spa Water," 1775; "Observations on Poisons and the Use of Mercury," 1784; "Observations on Mineral Poisons, with Cases" (Med. Comm.); "Observations on Canine Madness" (Ibid.), and "Remarks on the Hydrophobia and on the Ormskirk Medicine," 1786.

Dr. Bromfield, probably the alderman already mentioned, was interested in the salt water bath "at the Bath Hall and Coffee House," a description of which appeared in *Williamson's Advertiser* of June 18th, 1756; the advertisement, at any rate, was debited to Dr. Bromfield, according to the file copy of the paper, now extremely rare.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the last meeting of the Council the following document was signed by all the members of the Council present, but we were unable to publish it in our report of the meeting as it formed part of a Parliamentary paper which had not then been presented to Parliament.

"We, the Council of the Royal College of Surgeons of England desire to impress upon Her Majesty's Government the urgent need for the adoption of measures to check the prevalence of venereal disease in the Indian Army.

"The extent to which the British troops in India are shown by official reports to be now infected with venereal disease not merely seriously impairs the efficiency of the Army in that country, but constitutes, we believe, a grave danger to the health of the nation at home.

"When we know that 13,000 soldiers, of whom only 4 per cent. are married, leave India every year, and that at least one quarter of them have been affected with constitutional syphilis during their service in India, we can realise the risks to which the civil population in this country are exposed when these men return home.

"It has been shown that in 1894 only 37 per cent. of the British troops in India had never suffered from any form of venereal disease, that 28 per cent. had been treated for syphilis; and that of late years there has been a rapid increase in the frequency of both the primary and secondary forms of syphilis, and also, in a marked degree, in the virulence of the disease. In face of such facts, it is difficult to overestimate the amount of suffering which must follow, not only in the near future, but in years to come.

"We therefore express our earnest hope that Her Majesty's Government may take effective means to check the ravages of a disease which not only undermines the constitution of those who contract it in the first instance, but, by reason of the many ways in which it may be transmitted, destroys the health and happiness of countless other persons, and induces in the children of those originally infected diseases of a most formidable character."

THE PLAGUE IN BOMBAY.

THE total number of cases of plague in Bombay since the outbreak of the epidemic is returned as 10,583, of which 8976 proved fatal. The mortality from all causes during the last week reported amounted to 1149, against 1139 in the preceding week.

The Secretary of State for India has received the usual weekly telegram from the Governor of Bombay, from which we extract the following:—"Deaths from all causes in Bombay city for the week ended April 2nd, 1099; reported plague deaths, 481. During the past week one European plague case in Bombay city, one death in Mofussil. At Karachi during the week ended April 2nd, 189 plague deaths; marked decrease in Trans-Lyari, but marked increase in Keamari and one quarter of town, and a few cases in and about cantonment limits. At Sukkur plague is established; 103 cases, 58 deaths during week; Plague Committee formed; special civil and military officers sent, and thirty English soldiers being sent. At Haidarabad practically no change."

We may add that the death-rate at Poona is decreasing, and that recoveries are becoming much more frequent than they were. House-to-house visitations in plague-infected districts, inspections, and preventive measures generally are being energetically carried out.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of this society was held on April 6th, at which the following resolutions were carried unanimously:—

"That the Association of Fellows and the 201 Fellows who voted in favour of extending the franchise to the Members be cordially thanked for their liberal-minded action, and this committee is confident that their example will be followed by the majority of Fellows on the next occasion."

"That a letter be written to the Association of Fellows stating that in the opinion of this committee it would be greatly to the interest of the College if steps were at once taken to invite Lord Lister to allow himself to be nominated as a candidate at the next Council election with a view to his becoming President of the College in July next."

"That the committee of this society observes with pleasure that the Council proposes to celebrate the Diamond Jubilee of Her Majesty in some fitting manner, and the committee trusts that this may take a form in which the Members generally may be able to participate."

"That the best thanks of this society be offered to Mr. Walter Rivington for his consistent advocacy for many years of the Members' claim to representation, and for the manner in which he has sacrificed his collegiate interests to promote the true welfare of the institution and of all connected with it."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6475 births and 3866 deaths were registered during the week ending April 3rd. The annual rate of mortality in these towns, which had been 18·7 per 1000 in each of the two preceding weeks, declined again last week to 18·3. In London the rate was 17·6 per 1000, while it averaged 18·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·6 in West Ham, 12·9 in Croydon, 13·1 in Derby, and 13·4 in Gateshead; the highest rates were 24·0 in Nottingham, 26·4 in Salford, 27·0 in Burnley, and 34·8 in Bolton. The 3866 deaths included 344 which were referred to the principal zymotic diseases, against 344 and 359 in the two preceding weeks; of these, 105 resulted from whooping-cough, 89 from measles, 66 from diphtheria, 28 from scarlet fever, 23 from "fever," (principally enteric), and 23 from diarrhœa. No death from any of these diseases was recorded last week in Swansea, in Birkenhead, or in Wolverhampton; in the other towns they caused the lowest death-rates in Norwich, Huddersfield, and Halifax, and the highest rates in Leicester, Manchester, Salford, and Bolton. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Burnley, Plymouth, Salford, and Bolton; from whooping-cough in Bristol, Leicester, and Manchester; and from "fever" in Derby. The mortality from scarlet fever showed no marked excess in any of the large towns. The 66 deaths from diphtheria included 41 in London and 3 in Salford. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns. There were 17 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 3rd inst., against 30, 29, and 21 at the end of the three preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital was 2512, against 2685, 2622, and 2585 on the three preceding Saturdays;

Hosted by Google

219 new cases were admitted during the week, against 218, 206, and 224 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 317 and 313 in the two preceding weeks, further declined last week to 282, and were 145 below the corrected average. The causes of 52, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Leeds, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Salford, Preston, Huddersfield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·3 and 22 6 per 1000 in the two preceding weeks, further declined to 22·1 during the week ending April 3rd, but was 3·8 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·4 in Paisley and 17 0 in Perth to 22·9 in Edinburgh and 24·1 in Glasgow. The 659 deaths in these towns included 41 which were referred to whooping-cough, 29 to measles, 17 to diarrhœa, 9 to diphtheria, 6 to "fever" (principally enteric), and 2 to scarlet fever. In all, 104 deaths resulted from these principal zymotic diseases, against 106 and 96 in the two preceding weeks. These 104 deaths were equal to an annual rate of 3·5 per 1000, which exceeded by 1·9 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 33 in each of the two preceding weeks, rose again to 41 last week, and included 28 in Glasgow and 9 in Edinburgh. The deaths referred to measles, which had increased from 27 to 36 in the three preceding weeks, declined again to 29 last week, of which 15 occurred in Glasgow and 12 in Edinburgh. The 9 fatal cases of diphtheria considerably exceeded the number recorded in any recent week, and included 6 in Glasgow and 3 in Edinburgh. The deaths referred to different forms of "fever," which had been 11 and 4 in the two preceding weeks, rose again to 6 last week, of which 5 occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 155 and 159 in the two preceding weeks, declined to 146 last week, but exceeded by 39 the number recorded in the corresponding period of last year. The causes of 45, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 40·4 and 36·1 per 1000 in the two preceding weeks, rose again to 38·5 during the week ending April 3rd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 40·2 per 1000, the rate during the same period being 18·4 in London and 22·4 in Edinburgh. The 258 deaths registered in Dublin during the week under notice showed an increase of 16 upon the number in the preceding week, and included 47 which were referred to the principal zymotic diseases, against 74 and 67 in the two preceding weeks; of these, 27 resulted from measles, 9 from whooping-cough, 4 from scarlet fever, 4 from diarrhœa, 2 from "fever," and 1 from diphtheria. These 47 deaths were equal to an annual rate of 7·0 per 1000, the zymotic death-rate during the same period being 1 6 in London and 5·0 in Edinburgh. The fatal cases of measles, which had been 46 and 37 in the two preceding weeks, further declined to 27 last week. The deaths referred to whooping-cough, which had been 20 and 19 in the two preceding weeks, further fell to 9 last week. The 4 fatal cases of scarlet fever exceeded the number recorded in any recent week. The 258 deaths registered in Dublin last week included 48 of infants under one year of age and 47 of persons aged upwards of sixty years; the deaths of infants showed a slight decline; while those of elderly persons exceeded the number recorded in the preceding week. Five inquest cases and 3 deaths from violence were registered; and 76, or nearly a third, of the deaths occurred in public institutions. The causes of 17, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR W. F. HEFFERNAN is attached to the Station Hospital, Poona, for duty. Surgeon-Captain C. G. Spencer has been posted to India, and Surgeon-Captain S. Powell to Aldershot.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the undermentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty: Surgeon-Captain C. T. Hudson (Bombay), Surgeon-Captain C. H. Bedford (Bengal), Surgeon-Captain C. Milne (Bengal), Surgeon-Captain E. A. Newman (Bengal), Surgeon-Lieutenant B. H. F. Leumann (Bombay), Surgeon-Lieutenant H. J. K. Bamfield (Bengal), Surgeon-Lieutenant V. B. Bennett (Bombay), Surgeon-Lieutenant S. Evans (Bombay), Surgeon-Lieutenant A. Hooton (Bombay), Surgeon-Lieutenant A. W. R. Cochrane (Bengal), Surgeon-Lieutenant N. R. J. Rainier (Bengal), Surgeon-Lieutenant W. J. Niblock (Madras), Surgeon-Lieutenant H. J. Walton (Bengal), Surgeon-Lieutenant A. E. H. Pinch (Bengal), Surgeon-Lieutenant J W. Cornwall (Madras), and Surgeon-Lieutenant W. G. Richards (Madras). The services of the undermentioned officers are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on plague and famine duty:—Surgeon-Captain A. W. Dawson (Bengal), Surgeon-Captain B. R. Chatterton (Bengal), Surgeon-Captain J. Mulvany (Bengal), Surgeon-Lieutenant C. H. Bensley (Bengal), Surgeon-Lieutenant J. C. Robertson (Bengal), Surgeon-Lieutenant C. D. Dawes (Bengal), Surgeon-Lieutenant C. B. Harrison (Madras), Surgeon-Lieutenant J. S. Stevenson (Bengal), Surgeon-Lieutenant A. Miller (Madras), and Surgeon-Lieutenant H. R. Brown (Madras). The services of Surgeon-Captain J. J. Bourke (Bengal) are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces for employment on plague duty. The services of the undermentioned officers are placed temporarily at the disposal of the Foreign Department for employment on plague duty: Surgeon-Major Jamshedji Kharshedji Kanga (Madras), and Surgeon-Lieutenant J. Stephenson (Bengal).

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Fleet-Surgeons: Theodore J. Preston to the Royal Victoria Yard, Deptford, and Richard S. P. Griffiths to Haulbowline Hospital. Surgeon Benjamin G. Heather to the *Virid*.

VOLUNTEER CORPS.

Royal Engineers: 1st Lancashire: Surgeon-Lieutenant J. M. Whiteford resigns his commission. *Submarine Miners:* The Clyde Division: John Rowan, M.B., to be Surgeon-Lieutenant. The Tees Division: Surgeon-Captain W. J. Williams M.D., resigns his commission. *Rifle:* 3rd Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant-Colonel G. Okell resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 3rd Volunteer Battalion the King's (Liverpool Regiment): Thomas Hammond Fisher, gent, to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment) Surgeon-Lieutenant S. Lodge, M.D., to be Surgeon-Captain. 3rd Volunteer Battalion the Cheshire Regiment: Lieutenant Charles Adolphe Knowles Renshaw resigns his commission, and is appointed Surgeon-Lieutenant; Edward John Sidebotham, M.B., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Northamptonshire Regiment: Herman Stedman, M.D., to be Surgeon-Lieutenant. 9th Middlesex: Charles Ernest Goddard, gent., to be Surgeon-Lieutenant. 3rd Volunteer Battalion (the Manchester Regiment): Surgeon-Captain J. Duncan, M.B., to be Surgeon-Major. 1st Sutherland (the Sutherland Highland): Surgeon-Lieutenant J. B. Simpson to be Surgeon-Captain. 6th Volunteer Battalion the Gordon Highlanders: Alfred Bell Whitton, M.B., to be Surgeon-Lieutenant.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain J. Duncan, M.B, to be Surgeon-Major. Surgeon-Lieutenant Hugh Dickie, M.B., 1st Volunteer Battalion the Northumberland Fusiliers to be Surgeon-Captain. Surgeon-Lieutenant William Pemberton Peake,

Hosted by Google

1st Volunteer Battalion the Leicestershire Regiment, to be Surgeon-Lieutenant.

THE HEALTH OF THE TROOPS IN INDIA.

The *Times* of the 1st inst. publishes an analysis of the memorandum which has just been issued by the British Committee of the Federation for the Abolition of the State Regulation of Vice, signed by the chairman, Mr. Walter S. B. Maclaren, and accompanied by a "brief statement as to the nature and tendency of the Contagious Diseases Acts and why their re-introduction should be resolutely opposed." The committee recognise the seriousness and difficulty of the situation, and although they declare a return to the old regulation system to be impossible, not only because it encouraged vice, but because it failed in its object, they are not in favour of a do-nothing policy. What, in their opinion, must be done is to attempt honestly to diminish the vice which is the cause of the disease. To this end moral character should be made an important element in promotion; a man's "medical history sheet" should be taken as an indication of character in the same way as the "defaulters' sheet," and regiments in a specially bad condition should be treated with special discipline. Further, a Select Committee should consider how the moral tone of the Army can be raised amongst both officers and men; how further occupation and recreation can be provided; why the percentage of married soldiers is so much smaller than it used to be; whether a longer service system for older men is feasible or desirable; why the numbers of cantonment hospitals and cantonment general hospitals have so greatly decreased; how the contraction of disease may be made more difficult; and why the admissions to hospital vary so much in different stations and different regiments. The committee point out that anything on the lines of the Act for the Notification of Diseases and the detention or imprisonment of persons in hospitals would lead to improper denouncing in certain cases and blackmail. They object to any scheme which necessitates the examination of women, and are prepared to resist to the uttermost such a system as that of the Cantonments Regulations.

GUN-SHOT WOUNDS DURING THE MADAGASCAR EXPEDITION.

That the late Madagascar war cost the French dear is unfortunately well known, but not many of the casualties were due to the weapons of the enemy. According to a return which has just been published by order of the War Minister 46 men belonging to the flying column were treated for gun-shot injuries in the ambulance which was established at Isoavinandriana in the building formerly occupied by the English hospital. The strength of the column which left Andriba on Sept. 14th, 1895, was 237 officers and 4013 men, with 1515 non-combatant followers. It was not until the 26th that the first batch of wounded, consisting of 6 men, reached the ambulance. On the 28th 5 arrived, and the next day 5 more. The final consignment, 30 strong, was received on the 30th; 44 men out of the 46 were wounded by soft lead bullets fired from breech-loading rifles of a large calibre. Two men only were struck by small bore projectiles of the Winchester pattern. The shells that were discharged by the Hova artillery were badly aimed and seldom or never burst; no one was injured by them. Five deaths took place among the wounded, a result which, considering the bad health of the troops and the hardships and privations they were exposed to, must be regarded as highly creditable to the medical officers of the ambulance. Only one amputation was performed, the 40 remaining cases recovering without the loss of a limb.

THE "ALEXANDER MEMORIAL FUND" PRIZE.

The prize of £50 and the gold medal for the "Alexander Memorial Fund" for 1896 has been awarded to Surgeon-Major Cecil Birt, Army Medical Staff. The subject for the next competition is "Injuries to Joints and Long Bones caused by Modern Small Arm Projectiles; their Nature, Diagnosis, and Treatment, with special Reference to the Appliances Required and Available on Field Service." Essays must reach the President of the committee on or before December 31st, 1899. Essays are to be legibly written, superscribed with a brief motto, and accompanied by a sealed envelope similarly superscribed, containing the name and address of the author. No essay shall exceed in length fifty pages of ordinary printed octavo, which may be estimated as amounting to 20,000 words. This limit is exclusive of tables, which may be added in the form of appendices. The competition is limited to executive officers of the Army Medical Staff on full pay; but professors and assistant professors at Netley are not allowed to compete while so employed.

THE HEALTH OF THE TROOPS.

A Parliamentary paper has been issued showing the average annual strength of the troops at certain home and foreign stations in the years 1894 and 1895, with the admissions of soldiers to hospital and the ratio of admissions per 1000 of mean strength for all forms of venereal disease and the ratio constantly sick from such causes per 1000 of mean strength. From this return it appears that the ratio of admissions to hospital and of men constantly sick from all forms of venereal disease shows a decrease in the named years in the United Kingdom, in the West Indies (including Jamaica), and in Egypt; but an increase in Gibraltar, Malta, Canada, Bermuda, South Africa and St. Helena, China and the Straits Settlements, and in India; while as regards Cyprus the ratio of admissions has increased, but of men constantly sick has decreased, and as regards Mauritius and Ceylon the opposite has taken place.

Correspondence.

"Audi alteram partem."

RIGHT-HANDEDNESS.

To the Editors of THE LANCET.

SIRS,—In his Lumleian Lectures on Aphasia Dr. Bastian makes allusion to right-handedness and its probable influence on the localisation of the speech faculty in the left cerebral hemisphere, and he says, in effect, that none of the answers hitherto given to the question, "Why are we right-handed?" are altogether satisfactory. All are agreed that the causes of right-handedness are to be looked for in our remote ancestors, and an appeal is made to education and heredity as offering sufficient explanation. I believe that right-handedness is a necessity and depends upon the distribution of the weight of the viscera in the thorax, and that our four-limbed ancestors were right-pawed long before they began to stand on their hind-legs for oratorical or other purposes. The weight of the viscera in the left half of the thorax is considerably greater than that of those in the right half. This is evident in the dead body; but the contrast during life, when the heart is full of blood and the right lung is thoroughly inflated, must be far greater than it is after death.

When an animal stands upon its four limbs, the body being horizontal, it is evident that the centre of gravity of the thoracic cavity is nearer the left fore-limb than the right fore-limb, and that the stability of the body is more upset by taking the left fore-limb off the ground than it is by removing the right fore-limb off the ground. If an animal, therefore, wishes to make independent use of one of its fore-limbs, it probably chooses the right for that purpose, because by so doing it interferes very little with the stability of the body, and it is evident that unless the body be firmly planted on the ground the independent use of one of the fore-limbs cannot be really effective. A little child left to itself and crawling on "all fours" would for the same reason use the right arm by preference for purposes which are independent of locomotion.

I am, Sirs, yours truly,

Wimpole-street, April 8th, 1897. G. V. POORE.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—As far as facts and figures are concerned, Mr Clement Lucas's two long and genial letters furnish no additional arguments in favour of his views. My reading of Mr. Lucas's original article led me to the conclusion that he wished to establish some connexion between the occurrence of pneumonia and the administration of the anæsthetic, and my argument is that there is no reliable evidence in favour of this view, but that when the matter is critically examined it is seen to rest on mere tradition. There can be no two-

Hosted by Google

opinions as to the desirability of cleanly administration, but there is surely a far cry between this admission and the association in question. In matters bacteriological I see no shame in admitting that I am "a child," and for this reason I was careful not to give my own opinions, but, as the context showed, the opinions of leading authorities. Whether the opinions of Crookshank and Sternberg are accepted by modern physicians is a matter for the modern physicians themselves to determine; it is true, of course, that Crookshank's last edition is now a few months old, and many theories may have been advanced since then. The diatribe against the Clover's inhaler, quoted by Mr. Lucas, is, I fancy, not unknown even in this (anæsthetically) degenerate Western hemisphere, but it loses much of its force when we recollect that almost precisely similar invective may be directed against any surgical instrument or surgical procedure. Anyone who cares to take the trouble can clean, boil, or superheat a metal inhaler with ease, and, on the other hand, a surgical instrument in careless hands may become the very acme of all that is foul and filthy; the antiseptic process itself has been condemned because of failures consequent upon faulty technique.

I have the honour to remain, Sirs, your faithfully,

J. FREDK. W. SILK.

Devonshire-street, Portland-place, W., April 5th, 1897.

"AN UNDESCRIBED SYMPTOM."

To the Editors of THE LANCET.

SIRS,—In connexion with Mr. Battle's paper in THE LANCET of March 27th, "An Undescribed Symptom in Peritonitis," it may be of interest if I briefly describe a very similar case which I recorded in THE LANCET of May 10th, 1890, p. 1015, under the title of "An Unusual Case of Strangulated Hernia." A middle-aged man suffering from strangulated hernia was admitted into the General Hospital, Birmingham, under the care of Mr. Haslam, to whose courtesy I was indebted for permission to publish the case. The man's general condition was very much the same as that of Mr. Battle's patient. He was in a condition of collapse and could hardly answer questions, so it was difficult to get a history. His abdomen was distended, motionless, and tympanitic. Over the lower part of it was an œdematous swelling. The swelling occupied both groins, especially the right, and extended into the perineum as far as the base of the triangular ligament. The scrotum was swollen and tense. The swelling on the abdomen was limited towards the thighs by Poupart's ligament. The whole appearance was so like that produced by extravasation of urine that more than one surgeon who saw the case was inclined to make that diagnosis rather than the one of strangulated hernia, to which other symptoms pointed. The patient was placed under chloroform, and an incision over the right inguinal region showed a hernia of the small intestine. The gut was gangrenous and piebald in colour, though it had not given way. The sac was full of purulent fluid. The tissues over the sac were also infiltrated with fluid. The bladder and urethra were examined, but no extravasation of urine was found. They were quite healthy. The patient was now in a moribund condition, or the abdomen would have been opened and washed out. He died a few hours after. A post-mortem examination showed extensive suppurative peritonitis which had probably started in the hernial sac.[1] The condition of œdema was almost exactly like that which Mr. Battle describes. In both cases the symptoms appeared in a "late stage of the disease" and "indicated a very intense inflammation of the peritoneum." In future cases of the kind the bacteriology ought to be carefully worked out.

I am, Sirs, yours faithfully,

Hove, March 29th, 1897. D. R. P. STEPHENS F.R.C.S. ENG.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—Any one knowing much of epileptics—whether suffering from immediate traumatic epilepsy or transmitted (?) or obscure epilepsy—must know that even the best of them are quite unfitted for responsibility. They may be skilled up to certain points in music, art, literature, or manual work; but they are always subject to fits of more or less irresponsibility, they are always uncertain and not to be relied upon, and thus are quite unfit to have the training or hold the destinies of others in their hands. Thanking you in anticipation for your courtesy in giving my letter room,

I am, Sirs, yours faithfully,

MABEL ANDERSON, Lady Superintendent.

Meath Home for Epileptics, Godalming, April 3rd, 1897.

THE PROPHYLACTIC VALUE OF QUININE IN MALARIA.

To the Editors of THE LANCET.

SIRS,—I am reported in THE LANCET of April 3rd as having drawn attention, in a note upon Central African malaria, read before the Liverpool Medical Institution, to the "prophylactic value of small daily doses of quinine sufficient to cause slight aural disturbance." In discussing the prophylactic measures adopted by me in Central Africa, I gave a certain amount of credit to the exhibition of small daily doses of quinine, commenced at sea before entering the country and continued whenever the line of march lay along the course of low-banked rivers or cut across marshes or alluvial plains at a watershed foot. The doses were quite small, about four grains per diem, and were never pushed to the causation of symptoms.

The physiological index is of great value in the treatment of actual febrile manifestations. The personal equivalent being such an uncertain factor, it is impossible to lay down an unalterable dosage of quinine which will be applicable to all cases and which will yield universally good results. In two patients, under the same external conditions, suffering from malarial fever of the same type, a dose which will be quite effective in one may show little or no good in the other. In Central Africa it was found after experience that the best clinical results were obtained by apportioning to each individual such an amount of the drug as sufficed to produce in him an aural disturbance indicative of the commencement of quininism.

I am, Sirs, yours faithfully,

STANLEY KELLETT SMITH, F.R.C.S.,
Late Surgeon, Rhodesia Exploratory Expedition to Central Africa.

Liverpool, April 5th, 1897.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—It would seem useless to repeat arguments against midwives registration worn absolutely threadbare from reiteration. Nevertheless, as some of your correspondents appear to take an *ex parte* view of the scheme, may I offer a few remarks? Nobody can dispute that melancholy casualties occur at rare intervals from employing the Gamps—which, after all said, is only equivalent to having no attendance at all; but it is curious to note how the registration schemes have recently unearthed a state of affairs—i.e., the dire mortality due to Gamps—that nobody until quite lately seemed aware of. It should appear quite self-evident that if these fatalities exceed anything beyond rare occurrences the Gamps would not have held their own for so many generations past in country and other places where they have plied their craft, seeing how pronounced fatal cases of midwifery are. Further, if otherwise, it is impossible to conceive that in Continental countries where civilisation runs parallel with our own, and where legislative restraint has been at play for many years past, the mortality should exceed that of our own country. I am aware that certain undetermined factors such as contracted pelves, &c. (as amongst the Germans), have to be taken in to consideration; but it is preposterous to contend that these slender factors would suffice to strike a balance of mortality in favour of our own country if the damage due to midwives was anything like that represented by the witnesses who gave evidence before the Select Committee of the House of Commons. Granting, therefore, that I am correct in stating that the fatalities due to midwives are rare, I should like to ask Mr. Humphreys and his followers if such retrograde and revolutionary measures as the public have been edged on to anticipate are not likely to produce a greater mortality, taking all things into consideration, than already exists. I have remarked that the employment of Gamps is equivalent to having no attendance at all; but of what earthly use is it employing a registered

[1] I have not the report of the case by me, but my memory is very clear as to the above described symptoms.

Hosted by Google

midwife unless she is armed with ordinary therapeutic agents, such as antimony, ergot, opium, chloral, chloroform, or any other mortal drug? If she is allowed to use them she becomes, as Dr. Rentoul tersely puts it, a member of "an inferior order of medical practitioners"; if otherwise, and the State handicaps her from adopting the necessary treatment, the parturient woman might, and probably with greater safety would, be left in the hands of the Gamp. If, however, I am wrong as to these fatalities being rare—that is to say, the mortality being such as the promoters of registration appear to affect—let them then have the courage of their convictions, steer clear of all quackery, and move for an amendment of the Medical Acts so as to render it illegal for unqualified persons to practise midwifery for the purposes of gain—a procedure quite justifiable under such circumstances, and, moreover, consonant with the times, and infinitely preferable to bringing the rank and file of our profession in petty competition with a class of females; and God only knows (and I use the expression reverentially) where these will begin or where they will end.

I am, Sirs, yours truly,

Queen's-road, Peckham, April 3rd, 1897. CLEMENT H. SERS.

"A VERY GRAVE SCANDAL."

To the Editors of THE LANCET.

SIRS,—Having been favoured with a copy of THE LANCET and a marked paragraph in it, I fear I might not be showing that respect for your journal which I have always felt if I passed over in silence the matter underlying "A Very Grave Scandal." Whether some correspondent has veiled his inaccuracies under anonymity, or whether the matter is a cutting from a newspaper or an annotation of your own, there is not even so much as an inverted comma to indicate. Out of regard to my own time and your space I do not propose to correct inaccuracy, but content myself with answering the question which you put in the last sentence. I might have shown that my telegram was designedly sent in emphatic terms in order to prevent a very grave scandal. The question you want answered is—In case the man ran amok at the workhouse and killed someone, who would be responsible? The answer cannot be given in a word—it is a complex one. The persons immediately responsible would be the guardians, because the case was remitted to their care by the justice; then the justice, for making an order for the reception of a lunatic into a workhouse where there is (not) proper accommodation (see Sec. 21, Lunacy Act, 1890); but, taking them in inverted order, primarily the local authority (Sec 238, Lunacy Act, 1890). The local authority is defined in Sec. 240 of the same Act to be the council of every administrative county—a council which is well represented on the Eastbourne bench of magistrates; and, if I mistake not, one of its most influential members was the very justice before whom this might-be dangerous lunatic was taken. The county council, then, is the power you must arraign in your court of censure for not having provided asylum accommodation.

As the person, perhaps, more immediately concerned than any other individual in the trouble and annoyance due to want of asylum accommodation, I am not likely to make light of the incident described as a very grave scandal; but there are proper and improper ways of discussing it, and a good case needs no exaggeration to bolster it up. But, Sirs, "all's well that ends well," and instead of giving you the opportunity of inserting another sensational headline, there has been no "horrible discovery" or other tragic outcome of a lunatic being remitted to a workhouse for fourteen days (as other lunatics are constantly being sent for various reasons other than want of accommodation in the county asylums). Rather a comedy than a tragedy has been enacted; for when the lunatic in question was again taken before the justice so that a reception order might be made for his admission into the county asylum in which there was then a vacancy, the "dangerous" lunatic was allowed to escape. He did not "run amok," but made his way peaceably enough into another union, where, I am told, he is now detained. I repeat your question—If, when he was in charge of the workhouse officials and escaped from them, he had run amok, who would have been responsible? Sensational headlines are not in harmony with the usual matter we expect to find in THE LANCET; but I dare say the insertion of the paragraph which has called forth this answer will have served someone's purpose, although it has failed to secure your endorsement.

I am, Sirs, your obedient servant,

THE MEDICAL SUPERINTENDENT.

East Sussex County Asylum, Hayward's Heath, April 5th, 1897.

"THE OFFER OF THE 'ROYAL RED BOOK.'"

To the Editors of THE LANCET.

SIRS,—Our attention has been drawn to a paragraph in THE LANCET concerning the suggested introduction into our "Royal Red Book" of a list of the various physicians and surgeons practising specially. We should be greatly obliged if you would publish the notice that the scheme has been withdrawn entirely. On receipt of a great deal of correspondence commenting on it from all points of view we laid the matter before the Royal College of Physicians, who have condemned it, and it is therefore withdrawn without demur, and we have returned the subscriptions already received. At the same time we should like to point out that we raised the question, "Would it not be unprofessional?" and the professional gentleman who proposed it to us was of opinion that it would not. Moreover, we have received a good many orders from well-known medical men; we think, therefore, that we may fairly be excused for falling into the error, our desire being always to take advantage of suggestions we think likely to increase the usefulness of the work. We looked upon it as an ordinary subscription to a book. We trust that you will publish this letter in order that as many of the profession as possible may be acquainted with the facts, so that any sense of irritation they may still feel may be speedily allayed.

We are, Sirs, your obedient servants,

THE PROPRIETORS OF "WEBSTER'S ROYAL RED BOOK."

Piccadilly, April, 1897.

*** We are glad to learn of this very proper decision on the part of the Proprietors of the "Royal Red Book."—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Royal Infirmary.

THE election committee of the Royal Infirmary met on March 24th to fill up the vacancy caused by the resignation of Dr. Davidson. As was anticipated, Dr. James Barr, junior physician to the Liverpool Northern Hospital, was the successful candidate. The intelligence of the death of Mr. Heywood Bright, the recently appointed chairman of the Royal Infirmary, which took place on March 24th, after an illness extending over some weeks, was received in the city with much regret. His term of office as chairman was but of short duration, he having been elected as recently as Feb. 11th, in succession to Mr. H. B. Gilmour, who resigned at the annual meeting. He had never been able to preside over the meetings of the committee, as at the time of his election to the chair he was suffering from the illness which terminated fatally. The deceased was related to the late Dr. Bright, the physician who first accurately described the disease now so well known as "Bright's disease."

Liverpool Medical Club.

Dr. F. H. Barendt read a paper on Specialism before the members of the above club a fortnight ago. He treated his subject from four points of view: (1) specialism in general; (2) specialism in relation to the lay public; (3) specialism in relation to the general practitioner; and (4) specialism in relation to the specialist. In tracing the gradual growth of specialism he predicted that the general consultant would gradually be replaced by the specialist—in fact, many present consultants had attained eminence in the profession through the special study of some system or organ. He urged the importance of a knowledge of languages, and quoted Sir James Simpson in support of this qualification. With regard to the general practitioner, he ventured to suggest that in his consultations he should seek the advice of those who had become qualified by special study of the disease in question, and who avoided all semblance of entering into rivalry with him. He considered it futile to expect that the relationship between

Hosted by Google

practitioner and specialist should be on the same lines as that between solicitor and barrister in respect to practice. Patients would never admit such a relationship. On the other hand, he urged that general practitioners might do much to prevent patients leaving them by recommending them to specialists so soon as they detected any restlessness on their part; it would increase their own prestige and restore the confidence of the patient, and in many cases prevent the evil of hospital abuse. Pure specialism did not exist; the specialties themselves overlapped, and treatment itself was far more often general than special. On the other hand, the specialist should bear in mind his *raison d'être* and not compete with the general practitioner. The second annual dinner of this club will be held at the Adelphi Hotel on April 7th, when the chair will be taken by Mr. Mitchell Banks, the senior surgeon to the Royal Infirmary.

Donation to a Liverpool Charity.

Mr. T. Sutton Timmis has sent a donation of £1000 towards the building fund of the new Consumption Hospital on Mount Pleasant.

April 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Royal Infirmary.

THE official proposal by the Lord Provost to celebrate the Diamond Jubilee by the partial reconstruction of the Royal Infirmary on its present site continues to receive criticism from both professional and lay quarters. The suggestion already advanced in my letter in your issue of March 20th, that the opinions of the medical, surgical, and sanitary experts, upon whose advice the Lord Provost says he is acting, should be published, has been reiterated by numerous correspondents in the *Glasgow Herald*, but has failed to excite any response from the authorities, and it seems to be doubtful whether any detailed scheme has really been considered or planned. Thus at a recent meeting of the committee a letter was read from Dr. J. B. Russell, in reply to a request from the Lord Provost, stating that in his opinion the present site was quite suitable for a hospital, but expressing his inability to give any opinion as to its suitability for the reconstructed hospital until the plans of this had been submitted to him. It is certain that no local expert opinion would have greater weight with the public than that of Dr. J. B. Russell, and yet it would appear that no definite scheme was placed in his hands when he was asked for an expression of opinion on the official proposal. Under these circumstances it is not unnatural that some suspicion should arise as to whether any definite scheme has really been formulated. The promoters of the movement will be well advised to issue a frank and detailed statement at an early date. The public has a right to expect it, and without it success is scarcely possible. Already certain rival schemes are beginning to be pushed from various quarters. One of these is the proposal to raise a sum of money for the purpose of completing the Homes for Consumptives at Bridge-of-Weir. The construction of these, as far as they have been completed, is highly satisfactory, but Mr. Quarrier, who has raised the money for the homes and is practically the proprietor, appears to be strangely reluctant to consult the committee of medical men appointed to advise him on various matters. At least nothing is heard of this committee or its views or recommendations, and it is difficult to believe that its members approve of one part of Mr. Quarrier's plan—viz., the erection of a dispensary in Glasgow at the cost of £3000 for the treatment of out-door patients. The present infirmaries and dispensaries already offer ample opportunities for such treatment, and to spend £3000 on a new dispensary will be simply a waste of money. Certainly the profession generally will not extend confidence to the proposals of Mr. Quarrier unless he can show that they are endorsed by Professor Gairdner and the other members of the committee. It is true that there is one medical practitioner enthusiastically in favour of Mr. Quarrier's scheme; but in his letters to the local press he modestly signs himself "M.D."

University of Aberdeen: Honours to Medical Men.

For the first time in the history of the University the honorary and ordinary graduates were capped together on the 2nd inst. The graduation ceremony took place in the Mitchell Hall in presence of a brilliant audience. Among those who received the degree of LL.D. *honoris causâ* were Mr. Edward Albert Schäfer, F.R.S., Professor of Physiology in University College London, and Examiner in Physiology for various bodies; and Sir Thomas Grainger Stewart, M.D., Professor of Medicine in the University of Edinburgh. The same degree was also conferred in absence on Dr. Alexander J. C. Skene, one of the leading physicians in Brooklyn, a professor in the medical faculty and President of Long Island College Hospital, and author of various works and papers. In order to mark the new departure the members of the Senatus gave a "reception" in Marischal College in the evening, which was largely attended. On Saturday Principal Sir W. D. Geddes and Lady Geddes entertained to luncheon the honorary graduates, the two deans who were promoters, and Dr. Stephenson, Professor of Midwifery, the Senior Member of the Senatus.

April 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Queen's Nursing Home, Steevens' Hospital.

A VERY influential committee has been formed, and circulars have been widely distributed, for the purpose of raising a sum of £5000 to build and equip a Nurses' Home in connexion with this old-established hospital. It is proposed to lay the foundation-stone of the new building on the anniversary of Her Majesty's accession in June next.

Royal College of Surgeons in Ireland.

Dr. Thomas Myles has recently resigned the position of Professor of Pathology in the Medical School of the College of Surgeons. A successor will be appointed on the first Tuesday in May. A number of candidates are already in the field.

Health of Belfast.

The working of the new Notification Act brings out clearly the deplorably unhealthy state of Belfast, as during the four weeks from Feb. 25th to March 24th 358 cases of zymotic diseases have been reported, and of these 215 were typhoid fever, 53 scarlet fever, 26 measles, 24 erysipelas, 12 diphtheria, 12 simple continued fever, 6 membranous croup, 4 typhus fever, 3 whooping-cough, 2 puerperal fever, and 1 chicken-pox. The deaths from zymotic diseases were 75. As to typhoid fever, even the public officer of health admits he had no idea himself of the extent of the prevalence of this disease. No part of the city seems free from it, and, as Dr. Whitaker says, "I think that there is no city or town in the kingdom in which this disease prevails to such an extent as with us." Scarlet fever is still very prevalent, but the type is mild. It seems very strange that neither measles nor whooping-cough, though so infectious, is on the list of notifiable diseases as enumerated in the Act of Parliament.

The County Down District Asylum.

In his very full and interesting annual report for 1896 (just published) the superintendent, Mr. Nolan, reiterates the view he has expressed in previous reports that, notwithstanding the large increment of lunatics in asylums, there is no considerable real increase in insanity through the country generally, although in a current number of a monthly magazine, in an article entitled "Which is the Maddest Part of the Kingdom?" the writer answers, by statistical diagrams, "Ireland." Mr. Nolan's opinion as regards Ireland agrees with that of the Commissioners of Lunacy in their recent report as regards England.[1] In the Down Asylum there were 660 cases (336 males and 324 females) under treatment during 1896. The number of cases admitted was 128, being 10 less than in 1895, and 31 less than in 1894. This asylum is being much enlarged and improved, and the "Plenum" system of ventilation is being introduced.

Reformatory and Industrial Schools.

Mr. John Fagan, F.R.C.S. Irel., of Belfast, has been appointed Inspector of Reformatory and Industrial Schools, in place of Sir R. Blennerhasset, who has been appointed to the Presidency of Queen's College, Cork. Mr. Fagan

[1] THE LANCET, April 3rd, 1897, p. 968.

Hosted by Google

has for a lengthened time been surgeon to the Belfast Royal Hospital, a post which he will now resign. Professor Sinclair will be promoted, it is believed, and become a full surgeon, and Dr. Mitchell will get his place as senior assistant surgeon.

April 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Appendicitis at the Medical Societies.

THE question of appendicitis continues to occupy the attention of the societies. At the Academy of Medicine M. Reclus has sided with M. Lucas Championnière in what he has already said in opposition to M. Dieulafoy, and argues that in appendicitis the *rôle* played by a previous entero-colitis is a very important one. If this theory has been stated rather late it is because no one thought of establishing the relationship; and the cases cited by M. Dieulafoy where there was entero-colitis without appendicitis prove nothing, for they date from a time when appendicitis was not known or inquired into. It is probable, according to M. Reclus, that the co-existence of these two diseases is much more frequent than is generally supposed. He himself recently saw with M. Oettinger a case in which the etiology was as plain as if it had been a laboratory experiment. A young woman wishing to rid herself of some thread-worms had the foolishness to take an enema containing seven and a half grains of corrosive sublimate. Although she almost immediately afterwards took a second enema to bring away the first, she presented all the symptoms of acute enterocolitis, with griping pains and the passing of membranous shreds. Eight days later she was attacked by appendicitis with all the classical symptoms. M. Reclus referred to many other cases reported by such observers as M. Brissand, M. François Franck, and others, and he considers that now that attention has been directed to this subject we shall arrive at fresh knowledge. He considers that the stagnation of fluids plays an important part in some cases, as where there is a kink at the level of the neck of the appendix.

Two Interesting Debates.

Two important discussions have been going on at the Therapeutical Society recently. The first dealt with the intolerance of certain drugs displayed by some patients, in particular as regards antipyrin. M. Lyon, M. Dalché, and M. Duchenne reported cases of stomatitis, pemphigus, and various rashes produced by antipyrin. M. Blondel related a case where the use of antipyrin produced buccal lesions in a woman exactly like mucous plaques and also a rash resembling syphilitic roseola, so that the diagnosis from syphilis was rendered very difficult. The majority of patients with this idiosyncrasy had no albuminuria, so that it did not seem to depend upon faulty elimination, but rather on some particular predisposition of the subject. It was possible that in many cases the digestion was at fault, for, on the one hand, these accidents more rarely followed the use of antipyrin in solution than as a powder, and, on the other hand, the drug was much better tolerated if given with bicarbonate of soda or some intestinal antiseptic. The second subject discussed was chlorosis and its treatment. M. Barbier read an important report dealing with all the various theories as to the causation of chlorosis. M. Fernet spoke of the various general intoxications which may bring about the same condition. M. Huchard strongly advocated the least possible use of drugs in treatment, but the employment of fresh air, rest, and strict hygiene. M. Albert Robin opposed the opinion advanced by M. Hayem, who distinguished two periods in chlorosis—that of "déglobulisation," when iron is harmful, and that of "reparation," when it is of the greatest service. M. Robin divided the anæmic, in whom oxidation is very slow, from those in whom the exchange of oxygen is very rapid. Iron he considered good for the first group and arsenic for the second, for these drugs have directly opposite properties, and it is important not to give the one in place of the other. The chemico-biological state of the patient is the guide as to which drug shall be employed. M. Bardet recommended the administration of hæmoglobin in preference to any other form of iron, it being easily assimilable. At the last meeting of the society M. Blondel spoke upon chlorosis considered as an intoxication produced by the absorption of the products of the secretion of the ovary—a very modern view. M. Blondel considered that it is not amenorrhœa which causes chlorosis, but chlorosis which causes amenorrhœa, and that the consequences of this last, which are always the same, whether in the natural menopause, or after castration, or from retarded puberty, are added to the symptoms proper to chlorosis, but must not be confounded with them. Amenorrhœa appears in chlorosis as in many other dyscrasias, such as tuberculosis, malaria, and enteric fever. The secretion of the ovary cannot itself be the poison of chlorosis, as Charrin had argued in that society; for the internal use of ovarian extract had a good effect in chlorosis, as he himself had found in common with Spillmann, Jacobs, Etienne, and others. However, the frequency with which chlorosis occurs in young women just at the time of puberty made it obvious that the genital function had something to say to it. M. Blondel considered that chlorosis arose from some defect in the blood-forming organs, especially the red bone marrow, a tissue very easily influenced by various toxins and organic poisons, as is exemplified by the well-known fact that infectious fevers accelerate the growth of children. It is possible, he thought, to make use of the well-known antagonism existing between the internal secretions of the thyroid and the ovary. That action of the thyroid which is known to increase the growth of the skeleton and so govern the bone marrow has for a counterpoise the secretion of the ovary which comes into play at puberty, causes the disappearance of the thymus, and stops osseous growth. If this secretion is ineffective or remains in abeyance the action of the thyroid and thymus are prolonged beyond the necessary limits, organic oxidation is delayed, the osseous growth goes on, the bone marrow is "fatigued," the blood formation suffers, and the alteration of the corpuscles (together with the insufficiency of oxidation) will partly explain the classic phenomena of chlorosis. In such cases M. Blondel recommended the restoration of the ovarian function by the use of ovarian extracts, hydro-therapeutics, bicycle riding, and similar exercise. He also spoke well of the administration of iron and extract of bone marrow.

The Generosity of Madame Charcot.

The widow of the late Professor Charcot has resigned the annual pension of 2000 francs which she received from the State in favour of other widows and children of professors or *Agrégés* of the Faculty of Medicine of Paris who have died without leaving provision for their survivors. Madame Charcot has refunded all the money that she has received from the pension since the death of her husband.

Hospitals for Tuberculous Patients.

The authorities of the *Assistance Publique* have adopted in its entirety a plan for dealing with this subject drafted by M. Grancher and M. Thoinet. Special wards for tuberculous patients are being erected in three hospitals (the Lariboisière, the Tenon, and the Laënnec) to accommodate 600 patients. Three sanatoria are being constructed in other hospitals (the Broussais, the Cochin, and the St. Antoine) which will afford room for 600 more. Special precautions will be taken in the waiting-rooms, and deep spittoons will be lavishly provided. The idea of founding a special hospital at Brévannes has been abandoned owing to the opposition of the residents.

The Cost of the Plague.

The Chamber has unanimously passed a Bill to allow a sum of 297,000 francs to be set aside for the payment of expenses incurred on account of defensive measures taken against the plague. The introducer of the Bill, M. Bouge, congratulated the Chamber on the success of the measures proposed by France at the recent Sanitary Conference.

April 5th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The New Tuberculin.

A GREAT sensation was caused by the announcement made by Wolff's Telegraphic Agency that Professor Koch has discovered a new and powerful remedy against tuberculosis, and the last number of the *Deutsche Medicinische Wochenschrift* contains a detailed account of the investigations on the treatment of tuberculosis with which he has been

Hosted by Google

engaged since his first publications on the subject appeared in 1890. In the introductory part of his paper Professor Koch makes some general remarks on immunisation, saying that—unlike cholera, typhoid fever, &c., which confer immunity against subsequent attacks—an infection by the tubercle virus predisposes to new attacks of tuberculosis. But there are nevertheless indications that under certain circumstances an immunisation may take place. These circumstances are present in the experimental tuberculosis of guinea-pigs and in the general miliary tuberculosis affecting the human subject, where at a certain stage the bacilli completely disappear. Immunisation is therefore apparently attained when the whole body, as in general tuberculosis, is invaded by great masses of tubercle bacilli and when these bacilli come in direct contact with normal tissue. Professor Koch accordingly endeavoured to produce analogous bodily conditions in the hope of arriving at artificial immunisation. He first experimented by extracting tubercle bacilli with decinormal caustic soda. The fluid obtained in this way was not free from bacilli, for in a field of the microscope there were from five to ten of them to be seen, lying separately, not in heaps; they were, of course, dead. This preparation is designated as TA (i.e., Tuberkulin, Alkalisches), and produces when administered reactions quite similar to those of the old tuberculin of 1890; relapses were, however, less frequent. But there was one drawback: when more than a certain dose was given suppuration occurred at the place of the injection, the abscesses being due to the presence of dead tubercle bacilli in the preparation. The fluid was therefore filtered and the bacilli completely removed; when this was done suppuration was avoided, but the action of the TA was still identical with that of the old tuberculin of 1890. As, moreover, the fluid was easily spoiled and required constant fresh preparation, Professor Koch finally abandoned the TA and proceeded to other experiments. Having found that normal tubercle bacilli are not easily absorbed by the organism, he endeavoured to facilitate their entrance into the body by mechanical means. He has made the very interesting discovery that the bacilli are covered with a layer of a fatty acid which makes their absorption difficult, and which must therefore be previously removed. This he accomplished by triturating dried cultures in an agate mortar. After some time only a few bacilli remained entire, and they were got rid of by dissolving the mass in distilled water and treating the solution in a powerful centrifugal apparatus. In this way the fluid was divided into two layers: (1) an upper one not containing any tubercle bacilli, and designated as TO (i.e., Tuberkulin, Oberst); and (2) a lower one, which consisted of a colloid sediment with a few bacilli, and was designated as TR (i.e., Tuberkulin, Rest). The TR was then again dried, pulverised, and treated as before in a centrifuge, the process being repeated till the last bacillus was destroyed and the whole fluid became perfectly transparent. This product caused no suppuration and was easily absorbed. The action of TO is very like that of the old tuberculin and the TA, with the exception that it does not cause suppuration. Its immunising action is very slight, whereas that of the TR is very marked. When an excessive quantity is administered to tuberculous patients it, of course, sets up reaction, both local and general, but its immunising effect is quite independent of this; whilst with the old tuberculin and with the TA and TO reactions are necessary for an immunising effect. Such reaction must be avoided in TR. A man immunised by TR does not show any reaction when he is treated with TO and TA, so that he is immunised against every constituent of the bacillus. For the preparation of TR the most virulent and recent cultures must be used. The processes are very dangerous owing to the fact that living bacilli of high virulence have to be pulverised in an open mortar; indeed, Professor Koch felt as anxious as if he had to do with an explosive substance, and he points out that in making tuberculin on the large scale every care must be taken to prevent the bacilli from being scattered about, adding that this can only be done in a large factory. The Hoechst factory has been entrusted by him with the preparation of the TR. In making use of the TR it is administered by injection into the back with a well sterilised Pravaz syringe. One cubic centimetre of TR, containing 10 milligrammes of the dry substance, is mixed before use with weak sodium chloride solution, and in the first injections $\frac{1}{100}$ milligramme of the substance is given. Injections are to be made every second day, and the dose is progressively increased until it amounts to 20 milligrammes. When the temperature rises the injections must be stopped for some time. Guinea-pigs treated in this way were so completely immunised that injections of virulent cultures had no effect on them. When TR was administered after an injection of tubercle bacilli a marked regressive metamorphosis of the tuberculous organs was observed. Full immunity is only attained two or three weeks after the administration of the maximum dose both in the case of the lower animals and in the human subject. In the beginning of the treatment there is no apparent effect and no impression is made on the tuberculous state until half a milligramme or one milligramme has been given, so that patients who are likely to live only a few months should not be subjected to the treatment. Also patients suffering from secondary infection by streptococci and those in whom septic processes complicate the tuberculous affection will not derive any benefit from it. Temperatures exceeding 38° C. (100·4° F.) indicate a mixed infection and thus render the patient unfit for the TR treatment. Professor Koch has administered the TR to a great number of patients, especially sufferers from lupus, and in nearly every instance an improvement occurred—he did not say a "cure," because the time during which a relapse might take place was not yet past. In lupus it was especially remarkable that, notwithstanding a very small local reaction, the disease became less. This result is the reverse of that which was found to occur with the old tuberculin, where the therapeutic effect depended on the degree of the local reaction. In pulmonary tuberculosis the only local reaction observed after the administration of TR was a temporary increase of the catarrhal symptoms. After a few injections the sputum decreased in quantity, and at last it disappeared. In no instance did the general health suffer, nor were any undesirable symptoms observed. The patients' weight increased, and their temperature remained normal. Professor Koch concludes that probably the methods of administration may be improved, perhaps by combination with serum; but he thinks it will be impossible to improve the preparation itself.

It is to be hoped that Professor Koch's work, which undoubtedly is of the highest theoretical interest, will prove to be of practical value. The public and the lay press, remembering the collapse of the expectations aroused in the year 1890, are rather reserved on the subject, so that disappointments similar to those of the first tuberculin era will probably be avoided.

April 6th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Price of Panic.

"WHAT the 'pestis bubonica' costs the Treasury" is at present agitating Italy, whose impecuniosity can ill bear the additional burden of diminished harbour dues and money compensation for excess of sanitary jurisdiction. The opening of the year found her, principally at her seaports, quite "off her head" from panic at the apprehended invasion of the "pestis bubonica," in illustration of which the following incident and its financial sequelæ are not likely to be soon forgotten. On Jan. 22nd there arrived at the harbour of Ancona the English steamship *Glenorchy* with a cargo of jute, hailing from Calcutta. According to the regulations issued by the Board of Maritime Sanitation on Dec. 29th preceding, and applicable, as against the importation of the "pestis," to all ships hailing from countries beyond the Straits of Bab-el-Mandeb, the *Glenorchy* was forthwith subjected to sanitary inspection and to all the prescribed disinfecting processes. These being duly performed and certified the *Glenorchy* on the afternoon of the same day was admitted to "free course" (*libera pratica*). That evening, however, there reached the Prefect of Ancona a telegraphic order to send to the sanitary station of Alberoni, in Venetian waters, for visitation and disinfection, all ships arriving from British India. This order, as a prophylactic measure, was, in consequence of information received by the Prefect and of instructions forwarded from Rome, declared applicable to the *Glenorchy*. There arose, in fact, the

Hosted by Google

doubt, after that ship's admission to "free course," whether the said admission was legal. This doubt was more than accentuated by the panic in Ancona due to an arrival from suspected shores—a panic which seems to have been shared by the law advisers of the Commune, who threatened to absolve themselves of all responsibility should the dreaded consequences ensue on the admission of the *Glenorchy* to free course being sustained. So, "*per assicurare anzi tutto la tutela dell' ordine pubblico*" (to ensure above all things the safeguard of public order), the *Glenorchy* was made to comply with the detaining ordinance. Against this, however, her captain, in the name of the eminent London house which employed him, formulated a regular protest, and this in due course came before the Italian Government. The captain's plea was found, on expert consideration, to be, indeed, a strong one, and the Government, convinced of the advisability of avoiding an appeal to the law courts, and in consequence of negotiations conducted between the Minister of Foreign Affairs and H.B.M. Ambassador, Sir Clare Ford, saw it expedient to accept the claim for indemnity advanced by the captain, to pay him 10,000 lire (£400), and to quash all further procedure on account of the enforcement of the detaining ordinance against the *Glenorchy*. As I have said, the incident has made a profound impression on a kingdom chronically suffering from what Lord Beaconsfield called "that ignoble melancholy arising from pecuniary embarrassment"; and even if the findings of the International Sanitary Conference were less significant than they are against "excess of sanitary jurisdiction," the mulcting of the Treasury in £400 for what was simply a concession to unenlightened panic will teach Italy a lesson she stood much in need of. In fact, she is gradually coming to see that sanitary and hygienic reform is a much less expensive policy than her traditional system of "maritime boycotting," and that if she were better protected at home she would have less reason to dread epidemic invasion from abroad.

Psittacosis.

The "pestis bubonica" has had its pathological "side-lights," and one of these has been the demonstration—formerly a vague suspicion—of the power possessed by lower animals of conveying infective disease. A curious illustration of this power comes from Genoa, where the Civico Ufficio d'Igiene has just had to warn the citizens by circular against keeping parrots as domestic pets. A family named Rivalta in that seaport had been presented with one of these birds, and shortly thereafter its members, one after the other, became affected with broncho-pulmonary symptoms which took a rapidly "pernicious" course, carried off the father and mother, and placed the rest of the household in imminent danger of their lives. Similar cases of pneumonia, traced to the same cause, threw the population into panic, to allay which the Civic Office of Hygiene had to intervene with the following manifesto: "Parrots are susceptible of a peculiar infective disease very easily communicable to persons coming in contact with these birds when so affected. The disease, known by the name of 'psittacosis,' betrays itself in marked broncho-pulmonary disorder which very often runs a fatal course. Two parrots, recently arrived in Genoa by the steamship *Manilla*, set up two 'focolai' (centres of infection) of the aforesaid disease, and this has caused a number of victims. The best mode of avoiding so grave a risk is not to keep parrots; when they cannot be parted with all caressing of them or contact with them should be discontinued, especially if they show signs of malaise. In this latter case recourse ought at once to be had to the Uffizio Municipale d'Igiene. Such precautions are all the more indispensable as, in the day now passing, there have occurred cases of 'psittacosis'—a grave but easily avoidable malady." Some three years ago THE LANCET [1] described the illness and death from broncho-pneumonia of a well-known Florentine family, supposed to have contracted ptomaine poisoning from the consumption of unsound fish. At the time there was a counter explanation of the malady on the part of more than one consultant, who traced it to the presence of parrots as domestic pets in the household. This latter theory, which, in spite of the medical certificate, had strenuous supporters, seems to derive confirmation from the Genoese incident, and the case it accounted for may henceforth be cited as one, not of "death in the pot," but of "disease in the parrot."

April 4th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Physicians' Claims against Patients' Estates.

A BILL has been introduced into the New York Legislature having for its object the compulsory payment of physicians' bills against estates of dead patients. It provides that every executor and administrator must proceed to pay the debts of the deceased in the following order: (1) Debts entitled to a preference under the laws of the United States; (2) taxes assessed on the property of the deceased previously to his death; (3) debts of the deceased, because of services rendered and materials furnished by physicians, pharmacists, nurses, and undertakers; (4) judgments docketed and decrees entered against the deceased according to the priority thereof respectively; and (5) all recognisances, bonds, sealed instruments, notes, bills, and unliquidated demands and accounts. Preference shall not be given in the payment of a debt over other debts of the same class, except those specified in the fourth class. All debts specified in the third class shall become due upon the death of the deceased and shall be paid within ninety days thereafter.

Compulsory Reports of Cases of Phthisis.

The action of the New York Board of Health requiring physicians to report all cases of tuberculosis has excited much opposition in the profession. The committee on hygiene of the Medical Society of the County of New York, however, endorses the recent mandate of the health board concerning compulsory notification of cases of pulmonary phthisis as follows: "Realising the need of proper measures to prevent the spread of pulmonary tuberculosis, and regarding it as an essential preliminary that all physicians be impressed with the importance of making an early diagnosis of the same by microscopical examination of the sputum, we earnestly recommend that physicians avail themselves of the offer of the bacteriological department of the board of health to make such examinations. We approve of the compulsory reporting of cases of pulmonary tuberculosis, if the inspectors are forbidden to visit or to have any communication with the patients without the consent of the attending physician, believing that the attending physician is capable of giving all necessary instruction."

The Contagiousness of Pulmonary Phthisis.

Colorado Springs, Colorado, in the Rocky Mountains, is a famous resort for phthisical patients. Dr. Solly of that city, son of the late Mr. Solly of London, thus speaks of the contagiousness of that disease in that climate: "At least a third of our population are consumptives. The town, which contains some 15,000 people, has been established twenty years. An inquiry made by disinterested physicians into the number of cases of consumption that were known to have originated in the town resulted in a report of twenty in all. Although it is probable that our brilliant sunshine and dry air more quickly destroys the vitality of the bacilli than your eastern atmosphere, yet in the poorer lodging-houses of the town there are many ill-ventilated rooms, inside or on the north side of the building, inhabited by consumptives and their families, where recklessness of expectoration and carelessness of ordinary cleanliness are marked features of their domestic *ménage*; yet cases of contagion do not average more than one a year. At Colorado Springs the consumptives mingle with the other residents of the city on all occasions, at church service, theatre, concerts, and in the over-heated and crowded rooms of private residences during social functions; they reside in the same hotels, boarding-houses, and private dwellings with those not afflicted with the disease, and no attempt at isolation has been made. Notwithstanding this apparent indifference on the part of the local authorities to the contagiousness of the disease, only twenty cases have originated in Colorado Springs in twenty years."

New York Saturday and Sunday Association.

The total of last year's collections was $22,190.76 from churches, and $58,919.45 from other sources. Bed patients numbering 30,700 were cared for. Of these 23,271 were free. Medical aid was given to 250,000 free dispensary patients. The executive committee in their statement set forth that the hospital expenses of the past year were $1,323,238.15, with an income of $292,581.83 from funds invested, from paying patients $299,996.79, and from the city $66,047.91. The

Hosted by Google

association now embraces thirty-eight hospitals, and the collection is divided among them on the basis of free work performed by them during the year preceding on behalf of the poor.

Fined for "Spitting" in the Cars.

The first case of arrest and punishment of a person for violating the health ordinance against "spitting" in the cars occurred a few days since in this city. A passenger on one of the street cars expectorated very freely and without regard to the ordinance which was posted conspicuously in the car. At length the conductor called his attention to the rule of the health board and requested him to comply with it. He at once became abusive and began to expectorate around the car, whereupon he was summarily ejected and handed over to the police. On the following day he was arraigned in the magistrate's court, where the conductor of the car preferred charges against him for violating a health ordinance. His defence was that he had a severe cold and was obliged to expectorate freely. The court fined him five dollars.

Quarantine Measures against the Bubonic Plague.

In view of the alarming nature and spread of the bubonic plague now prevailing in India and the adjacent countries, and in view of the danger of this scourge being brought to the United States, Congress has adopted a resolution that at any port or place in the United States where the Secretary of the Treasury shall deem it necessary for the prevention of the introduction of contagious or infectious diseases incoming vessels, vehicles, or persons shall be inspected by a national quarantine officer; such officer shall be designated or appointed by the Secretary of the Treasury on the recommendation of the Surgeon-General of the Marine Hospital Service; and at any such port or place no vessel, vehicle, or person shall be admitted to entry without the certificate of the said officer that the United States quarantine regulations have been complied with.

March 19th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Small pox at Melbourne.

FOR the second time during the last few years the strict quarantine regulations in force in Victoria have failed and small-pox cases have been landed in Melbourne. The steamer *Nineveh* was inspected by the port health officer at Port Phillip Heads, given a clean bill of health, and came up to Melbourne, where her passengers were landed. Some of the crew had, however, suffered from ill health of a suspicious character, and Dr. Gray, the assistant medical officer of the Board of Health, made further investigation and discovered that they were either suffering or convalescing from small-pox in a mild form. The ship was at once quarantined and the health authorities, with the assistance of the police, succeeded in tracing almost all the passengers, who were placed in quarantine and vaccinated; and the action taken was so prompt and energetic that apparently no harm has been done. The occurrence, however, shows the necessity of appointing a man with special knowledge to the position of port medical officer, which is being temporarily filled until a permanent successor is appointed to the late Dr. Browning. At present there are three port medical officers—one at "The Heads" and two at Williamstown—and most of the large steamers and mail boats are examined at the latter place. It is suggested that all vessels should be examined at "The Heads," as was formerly the custom.

The Health of Sydney.

The annual report of the medical officer of the Sydney Water and Sewerage Board (Mr. Kendall) stated that, although the year 1896 exhibited remarkable extremes of heat and cold and great unevenness of rainfall, the general health of the metropolis was much improved, and notwithstanding the increase of typhoid fever during the year the general death-rate was lower than in preceding years. The zymotic death-rate had fallen from 2·4 per 1000 in 1895 to 1·3 in the city, and in the suburbs from 2·6 to 1·1. The mortality from diarrhœa had fallen from 7·0 per 10,000 to 6·1 per 10,000, and, as before the installation of the water and sewerage system the rate was 10·5 per 10,000, it was only fair to attribute at least a portion of the good result to the operations of the board. The mortality from diphtheria showed only a small decrease, and in certain districts it appeared to be endemic. Still, as the board had been extending its operations the mortality had fallen from 4·1 per 10,000 to 2·07. The mortality from phthisis in the metropolis had been reduced during the last nine years from 20 to 10·5 per 10 000. The death-rate from typhoid fever had increased to 4·2 per 10,000 from 1·92 for 1895. Mr. Kendall is inclined to ascribe the continued prevalence of typhoid fever to the breaking up of sewage-soaked soil in the extension of the sewerage works. More than half the cases did not arise in the city, but came from outside to get treatment. Typhoid fever was exceptionally prevalent among school children, and Mr. Kendall urges a thorough investigation of the sanitary condition of schools, and the Education Department has accordingly undertaken to reorganise the sanitary arrangements of the public schools

Phthisis in New South Wales.

In the year 1894, 1 in 14·5 of the total deaths, or 1 in 1201 of the population, of New South Wales was due to pulmonary phthisis, and of the total 1042 deaths 494 of the deceased persons were born in Australia, and only 71 had been less than five years in the colony. Practically hardly any accommodation is provided for cases of phthisis. The general metropolitan hospitals and convalescent homes only admit cases for the relief of temporary complications, and a small but varying number are admitted. During the last three years at the Prince Alfred Hospital, Sydney, 20 per cent. of such cases died, the rest were discharged with the advice "to go into the country." But how are they to go? their only means of livelihood being in the towns. Some time ago Dr. Sydney Jones suggested the establishment of sanatoria in the country for such cases, but nothing has been done. Now Dr. Sawkins, medical superintendent of the Prince Alfred Hospital, has made another suggestion. Many country hospitals are situated in climates suitable for incipient and non-progressive cases of tubercle, they are maintained at the public cost, but are hardly ever more than half full; and Dr. Sawkins suggests that the unoccupied beds in these institutions should be utilised for the reception of suitable cases of phthisis to be sent there from the metropolitan hospitals.

The Board of Health and the Dairymen in New South Wales.

Under the Public Health Act for New South Wales, passed last November, the Board of Health was empowered to administer the Dairies Supervision Act, the provisions of which were made to apply to cream, butter, and cheese—in short, to the whole dairying industry. The Board has drawn up a manual of instructions for the dairymen, and its inspectors and veterinarians are investigating and reporting, with the result that a number of dairymen are protesting against the stringent clauses of the Act. These clauses have been really in operation since 1886, but the local authorities did not enforce them. Now the Board is compelling the municipal bodies to carry out the provisions of the Act. In some districts milk vendors have closed their business rather than comply with the requirements. On the other hand, the suppliers of dairy produce for export have all along observed the conditions laid down, and are glad to see them enforced on all.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Gonner and Dr. Burckhardt, *privat-docenten* of Surgery, have been promoted to Extraordinary Professorships.—*Erlangen:* Dr. Specht has been appointed Professor of Psychiatry in succession to Professor Bumm; and Dr. Heim of Würzburg has been appointed Extraordinary Professor of Hygiene.—*Kiel:* On the occasion of the centenary of the Emperor William I. Professor von Esmarch has been granted the title of Excellency.—*Lemberg:* Dr. Ladislaus Szymonowicz of Cracow has been appointed Professor of Histology and Embryology.—*Prague:* Dr. Boennecken of Bonn has been appointed Extraordinary Professor of Odontology, with charge of the Dental Institute; and Dr. J. Thomayer, Extraordinary Professor of Special Pathology and Therapeutics, has been granted the title of Ordinary Professor.—*St. Petersburg (Military Medical Academy):* Dr. A. Likhacheff has qualified as *privat-docent* of general pathology.—*Vienna:* Dr. Franz Chvostek, *privat-docent* of Internal Medicine, has been appointed Extraordinary Professor.—*Zurich:* Dr. H. Müller, *privat docent* of Internal Medicine, has been appointed Extraordinary Professor.

Obituary.

WILLIAM HICKMAN, J.P., M.B. LOND., F.R.C.S. ENG., D.L.

WILLIAM HICKMAN of 122, Harley-street, and Camberlot Hall, Sussex, Surgeon-in-Ordinary to the Duke of Saxe-Coburg and Gotha, died at his residence in Harley-street on March 27th. He was educated at University College Hospital and took the degree of M.B. of the University of London in 1860 and became a Fellow of the Royal College of Surgeons of England in 1861. While at the hospital he held the posts of house surgeon, house physician, and ophthalmic surgical assistant, while his essay "On Some Varieties and Effects of Cancerous Disease of Bone" gained for him the Liston Surgical Gold Medal in 1860. After a prolonged visit to the East, he returned to London and set up in general practice in Dorset-square, N.W. He was surgeon to the Western General Dispensary, and for a time surgeon to out-patients at the Samaritan Free Hospital. At this time he published various cases and observations in the medical papers and societies' transactions; among these there are two specially interesting cases of transposition of the viscera recorded in the twentieth volume of the Transactions of the Pathological Society. Mr. Hickman was a past president of the Harveian Society, and in his presidential address (1883) on "The Aids and Hindrances to the General Practitioner" he advocated two reforms which have since been adopted—viz., the addition of a fifth year's study to the medical curriculum and the direct representation of general practitioners on the General Medical Council. He had thoroughly at heart the welfare of the general practitioner, and in this address he suggested a post-graduate system for their benefit. His plan was that the younger members of the hospital staffs should teach the students, and that the seniors should devote themselves to lecturing and demonstrating to medical practitioners. In 1885 Mr. Hickman exerted himself to bring about the amalgamation of the two Royal Colleges of Physicians and Surgeons into a Royal College of Medicine with power to grant the degree of Doctor of Medicine. He wrote, spoke, and originated a memorial to the Presidents of the Royal Colleges in favour of this scheme, which has been such a burning question since. Mr. Hickman pleaded for a degree-conferring Royal College of Medicine which would be retrospective and admit all those holding the qualifications of the two London Colleges to an M.D. degree. It was not intended to supersede the University of London, but to promote the interests of the rank and file of the students of the metropolitan hospitals. His arguments were always dignified, convincing, and the outcome of sound, shrewd, common sense, and, though it is perhaps hardly generally recognised, he did much to improve the status and education of his professional brethren.

In the spring of 1892 he received the appointment, in succession to Sir Oscar Clayton, of Surgeon-in-Ordinary to H.R.H. the Duke of Saxe-Coburg and Gotha. In 1865 he married Emmeline, youngest daughter of the late Mr. Thomas Lea, and by her had one son, Dr. H. R. Belcher Hickman. The primary cause of Mr. Hickman's death was malignant disease of the sigmoid flexure; this necessitated colotomy in May, 1896. After this he temporarily improved, but before Christmas, 1896, signs of secondary growths in the liver appeared, and he died after some months of constant suffering in his sixty-first year.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ludwig Hollaender, Professor of Odontology and Director of the Dental Institute of the Berlin University, in his sixty-fifth year. In early life he had practised as a medical man in South Africa.—Dr. de Marbaix, in Louvain, in consequence of a malarial affection contracted in the Congo, where he had lived for some years, and is well known as the founder of the Bacteriological Institute in Boma and for his researches on the diseases of that part of Africa.—Dr. Michel Stukovenkoff, Professor of Dermatology in the University of Kieff.—Dr. Eugène Afanassieff, formerly Professor of Medical Pathology in Kieff.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in the subjects indicated, viz.:—

Monday, March 29th:

Anatomy and Physiology.—Robert Cyril Turnbull, student of London Hospital; Godfrey Russell Potter and Benjamin Gowing, Yorkshire College, Leeds; Thomas Adam and Herbert Alfred Mason Firth College, Sheffield; Charles Ferrier Walters, Claude Alfred Heath Gee, Frederick Williams Cotton, and Alfred Coleridge, University College, Bristol; Reginald Shirley Burd and Arthur John Awdry, Mason College, Birmingham; William Nicholson, John Hoyle, and George Edward Seville, Owens College, Manchester; William John Young, William Arthur Bailey, and Robert Jaques, University College, Liverpool; Cyril Raymond Mass, Oxford University and University College, Liverpool; and William Warwick James, Middlesex Hospital.

Anatomy only.—William Morgan James, Cambridge University; and Thomas Arthur King, Cambridge University and St. Thomas's Hospital.

Twenty gentlemen were referred in both subjects, one in Anatomy only, and three in Physiology only.

Tuesday, March 30th:

Anatomy and Physiology.—Ernest Russell-Risten and Ernest Wethered, St. Bartholomew's Hospital; Arnold Edward Soden, McGill University, Montreal, and St. Bartholomew's Hospital; Arthur Pearson, Alan Carpmael Ransford, Frederick Curtis, and William Howard Edwards, Guy's Hospital; Edwin Wallace Goble, Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Zebulon Mennell and John Wishart Little, St. Thomas's Hospital; Stanley James Kerfoot and Lewis Eccles Hertslet, London Hospital; Arthur Gentry Pitts and Burton Alexander Nicol, Charing-cross Hospital; Herbert Hugh Blair Cunningham, St. Mary's Hospital; Edward Mello Saunders, King's College, London; John Howard Addinsell, University College, Liverpool, and King's College, London; and William Wijeyesaker, Ceylon Medical College and University College, London.

Anatomy only.—Mr. Henry Joseph Butler, Carmichael College, Dublin, and St. George's Hospital.

Physiology only.—Walter George Douglas Miller, Cambridge University and University College, London; Leslie Frederick Enthoven, Cambridge University and Mr. Cooke's School of Anatomy and Physiology; Thomas Langton Butler, St. Mary's Hospital; and Orme Stirling Kellett, Cambridge University, London Hospital, and Mr. Cooke's School of Anatomy and Physiology.

Thirteen gentlemen were referred in both subjects, four in Anatomy only, and one in Physiology only.

Wednesday, March 31st:

Anatomy and Physiology—Reginald Gauld, London Hospital; Hugh Stannus Stannus, Robert James Harris, and Saville Waldron Hanbury, St. Thomas's Hospital; Suhrid Nath Chowdry, University of Calcutta and St. Thomas's Hospital; John Wilfred Nunn and Herbert Ernest Ashley, St. Bartholomew's Hospital; William Bastian and George William Morris Pritchett, University College, London; William Arthur Durance and Herbert Halliday, Westminster Hospital; William Vare Chalmers Francis, Westminster Hospital and Mr. Cooke's School of Anatomy and Physiology; James Frederick Robinson and Francis George Cross, Guy's Hospital; Iain Mackinnon Jefferiss and Dudley Beckit Truman, King's College, London; and Ernest John Manning, St. Mary's Hospital.

Nineteen gentlemen were referred in both subjects.

Thursday, April 1st:

Anatomy and Physiology.—Robert Dunstan, Alec Leslie Matthews, and Michael Foster Reaney, London Hospital; Albert Remington Hobbs, Ernest William Holyoak, Charles Hildred Brodribb, and George Barnes, St. Mary's Hospital; Herbert Raymond Bateman, John Coates, and Thomas Henry Edwards, St. Thomas's Hospital; Henry Arthur Bramsden Bransbury and Walter Fedde Fedden, St. George's Hospital; William Henry Loosely and Charles Edward Hicks, Guy's Hospital; Maurice Gilbert Hannay, Charing-cross Hospital; Robert Lewis Thornley and Alexander Robert Tweedie, St. Bartholomew's Hospital; Felix Anthony Boissiere and William Henville Lowman, King's College, London; and Charles Visger, University College, London.

Sixteen gentlemen were referred in both subjects.

Friday, April 2nd:

Anatomy and Physiology.—Roy Henry Rollinson Whitaker, Maurice Guy Winder, Francis Musgrave Howell, Ernest George Smith, Arthur Tregelles Pridham, and Charles Archibald Scott Ridout, St. Bartholomew's Hospital; Philip Hedgeland Ross, Otago University, New Zealand, and St. Bartholomew's Hospital; Edward Cohen, Robert William Basil Hall, and David Forsyth, Guy's Hospital; John Ford Northcott, Cambridge University and Guy's Hospital; Henry Lloyd Driver, John Aylward Churchill, and Thomas Crisp English, St. George's Hospital; Frederick Charles Carlé and Alfred Carleton Williams, King's College, London; Godfrey Brookes Dixon, Charing-cross Hospital; Sydney Pern, Archibald Douglas Jameson, and Sydney Hunt, St. Thomas's Hospital; Hardy Vesey Wells, St. Mary's Hospital; Norman Navarra, Middlesex Hospital; Alfred Richard Spencer and David Leighton Davies, University College, London; and Hermann Balean, London Hospital.

Twelve gentlemen were referred in both subjects.

Saturday, April 3rd:

Anatomy and Physiology.—Richard Horace Paramore, St. Bartholomew's Hospital; Ernest Henry Bonney and Sydney George

Hosted by Google

Harrison, Charing-cross Hospital; Edward Norman Tilly Rogers and Cecil Rodney Rickard, Middlesex Hospital; Percy Harold Ward, Guy's Hospital; John Tattersall, St. Mary's Hospital; Frank Miller Bingham, St. Thomas's Hospital; William Benjamin Batchelor Taylor, London Hospital; Laurence Jones, St. George's Hospital; and William MacLellan, Edinburgh University.
Four gentlemen were referred in both subjects.

UNIVERSITY OF GLASGOW.—The following have passed the Second Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (A., Anatomy; P., Physiology; and M., Materia Medica and Therapeutics):—

Robert Fisher Ballantyne (M.), James Napier Baxter (M.), James Freeborn Bennett (A., P.), Andrew Brownlie (A., P.), John James Buchan (M.), William Adam Burns (A., M.), Thomas Bullough Calland (P.), Ranald Douglas Campbell (A., P., M.), James Carruthers, M.A. (A., P., M.), James Robert Chalmers (A., P.), William Crerar (A.), John Cullen (M.), Charles Cheven Cumming (A., P.), John Ronald Currie, M.A. (M.), Archibald William Wallace Davidson (A. P.), David Curr Douglas (A.), James Drummond (A., P.), Binnie Dunlop (P., M.), Hugh Campbell Ferguson (A., P.), William Gibson (A., P.), James Garden Green (P.), David Sloan Harvey (M.), Thomas Inglis (P.), Nicol Jamieson (A., P.), Andrew Kerr (A., P.), Andrew Stewart Lang (M.), Robert Luman (A.), Ramsay Millar (A.), Hugh Miller (A., P.), Norman M'Leod Miller (A., P.), Ernest Wardlaw Milne (M.), James Hogg MacDonald (A., P.), Peter MacIntosh M'Fadyen (A., P.), John M'Gilchrist (A., P.), Charles Forbes Maclean (A.), Norman Forbes Macleod (A. P.), Alfred Robert Maclurkin (A., P.), John M'Millan (A., P.), William Gardner Neill (M.), Alexander Duncan Nicolson (M.), John Patton (A., P.), William Alexander Riddell (A., P.), Arthur Robin (A., P.), James Scott, M.A. (A., P.), James Shearer (A., P.), David Ap-Simon (P., M.), Andrew James Smith (M.), David James Smith (A., P.), James Smith (M.), James Johnston Smith (P., M.), Peter Alexander Steven (A., P.), Alfred George Stewart (A., P.), Andrew Taylor (M.), Charles Pinkerton Thomson (A., P.), William Brown Thomson (A.), Henry Nisbet Turner (M.), William Webster (M.), Alexander Simpson Wells, M.A. (A., P.), William Wright (A.), and John Doctor Young (A., P.). Women—Sarah Davidson (A., P.), Marjorie King Henderson Fleming (A.), Jessie Downie Granger (A., P., M.), Jane Grant (M.), Mabel Hardie (A., P.), Jessie Sophia Beatrix Hunter (P., M.), Ina Lochhead M'Neil (A., P.), Jean Effie Prowse (M.), Sara Maude Robertson (A.), Maude Spencer (A., P.), Gertrude Florence Fleetwood Taylor (A., M.), and Grace Lorrain Young (A., P., M.).

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

(*a*) *Including Pathology.*—John Donald, George Murray, Archibald Stevenson, and Alexander James Thompson Swann. (*b*) *Not including Pathology.*—John James Edgar, William Humphreys Jamison, George Moreland, James M'Caig, David Wallace Smith, and Alexander Waugh.

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

John Aitken (P., M.), George Alexander (P., M.), Alexander Smith Allan (P.), Arthur James Ballantyne (P., M.), Andrew Aitken Barclay (P., M.), William Bennett (P.), James Symond Beveridge (P., M.), George MacLellan Blair (P., M.), John George Wilson Boleyn (P.), Andrew Clark (P., M.), Robert Crawford (P., M.), Robert Douglas, M.A. (P., M.), Kenneth M'Kenzie Duncan (P., M.), James Finlayson Fleming (P.), Robert Fullarton, M.A. (P.), Alexander Garrod (P.), Harold Smith Heap (P.), John Henderson (P., M.), William Wallace Keir (P., M.), Alexander Lawrie (P., M.), Alexander Matheson (P., M.), James Blakely Miller (P., M.), James Alexander Mitchell (P., M.), Murdoch Macdonald (P., M.), Laurence Abel Mackenzie (M.), Roderick Reid Macnicol, M.A. (P., M.), James M'Whir (P., M.), Robert Niven (P., M.), Percival Leslie Pearce (P.), Joseph Wilkie Scott (P., M.), John Shaw, M.A. (P., M.), John Laird Simpson (P., M.), John Macfarlane Sloan (P., M.), Peter Donald Strachan, M.A. (P., M.), James Douglas Carnon Swan (P., M.), Daniel Rees Thomas (P., M.), Walter Lewis Thomson (P., M.), William James Alexander Walker (M.), Robert Andrew Hanan Watson (P.), Edward Roberts Weir (P.), James Patterson Wilson (P., M.), and William Wyper (P., M.). Women—Daisy Annabelle Bennett (P., M.), Agnes Forbes Blackadder (P., M.), Jane Lorimer (M.), Eva M'Call (P., M.), Minna Amelia Macfarlane (P., M.), Annie Louise M'Ilroy (P., M.), Margaret Wallace Howie M'Neil (P.), Mabel Catherine Poulter (P., M.), Agnes Renton Robson (P., M.), Marion Jamieson Ross (P., M.), and Sara Whiteford (P.).

UNIVERSITY OF ABERDEEN.—The degrees indicated have been conferred on the following gentlemen:—

Degree of M.D.—Edward Nicolls Carless, M.B., C.M., Devizes, Wilts, (under the new Ordinances); Frank Austin Gill, M.B., C.M. Rosskeen, Invergordon; *John Henry Goodliffe, M.B., C.M., Lancaster; Angus McGillivray, M.B., C.M., Dundee; William Mackie, M.A., M.B., C.M., Elgin; Leslie James Milne, M.A., M.B., C.M., Mirfield, Yorks; and Bertram Saunders, M.B., C.M., Exminster, Devonshire.

Degrees of M.B., C.M.—Forbes James Alexander, Aberdeen; John Wilhelmus Samuel Attygalle, Galle, Ceylon; Frank Hay Cantlie, Fochabers, Morayshire; William Lumsden, Aberdeen; Ronald Campbell Macfie, M.A., Old Aberdeen; James Mansie, M.A., Aberdeen; †Maurice George Robertson, M.A., Huntly, Aberdeenshire; William Alexander Salmond, Aberdeen; John George Stuart, Tarland, Aberdeenshire; George Fexil Thomson, Halifax, Nova Scotia; and Robert Valentine, Gourdon, near Montrose.

Degrees of M.B., Ch.B. (New Ordinances).—Robert Bruce, M.A., Myreton, Insch, Aberdeenshire; Alexander Ledingham, M.A., Boyndie, Banffshire; †Thomas William Lumsden, Midmar, Aberdeenshire; John Stewart Milne, M.A., King Edward, Aberdeenshire; Joseph Pozzi, M.A., Mintlaw, Aberdeenshire; and Thomas Snowball, M.A., Huntly, Aberdeenshire.

* Thesis considered worthy of commendation.
† With honourable distinction.

ANNUAL MEETING OF THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.—This meeting was held on March 27th. The executive committee were able to announce the receipt of a handsome donation of £1000 from the Baroness de Hirsch towards the formation of new branches. The report showed that the association had nineteen branches. The total number of cards was 10,619, showing a small increase on the previous year, with a corresponding increase in the members' payments, which now amounted to £4870. It was noticeable that the payments to the medical staff had increased in a greater proportion than the number of cards. In introducing the annual report the chairman, Mr. Bousfield, referred to the efforts that were being made to deal with the question of hospital out-patient departments. Some radical change could not much longer be delayed, and everything pointed to the probability that the work would be handed over to provident associations, friendly societies, and similar institutions. It was therefore of the utmost importance that the organisation of the Metropolitan Provident Medical Association should be complete when this time should arrive. An interesting experiment was made during the year. In view of the ever increasing number of applications for chest hospital letters the Hospital Saturday Fund made a special grant to the association, in return for which they undertook to sift the cases. The results of the inquiry were published in THE LANCET of March 20th, p. 820. Another matter of considerable interest to the medical profession was the endeavour to determine by means of a conference a fair rate of payments for women's provident medical clubs. Several meetings were held, but it was unfortunately found impossible to come to any definite conclusion. The chief cause in bringing about this abortive result was stated to be the want of organisation of the medical profession, in the absence of which it was impossible to reconcile conflicting interests.

PRESENTATIONS TO MEDICAL MEN.—Alderman J. B Richardson, J.P., M.D., C.M. Edin., L.R.C.P. Lond., &c., who was Mayor of Torquay during 1894-95, has been presented with his portrait in oils as a mark of appreciation of the manner in which he and Mrs. Richardson conducted the duties of Mayor and Mayoress. A bound album containing the names of 200 subscribers was given to Mrs. Richardson.—In recognition of his three contests for a seat on the Torquay Town Council Mr. E. Last Smith, J.P., L.R.C.S., L.R.C.P. Edin., was recently presented with an engraved silver salver and an illuminated address by a large number of friends.—At Bath, on March 20th, Mr. John Maurice Harper, M.R.C.S. Eng., was presented by the members of the Larkshall branch of the Rational Sick and Burial Friendly Society, of which he is the surgeon, with a handsome spirit case on the occasion of his marriage. The Mayor of Bath was to have presided at the meeting, but was prevented by illness. His worship, however, sent a kindly letter to Mr. Harper, with a handsome gold pin.—At a well attended meeting of residents in Torpoint and neighbouring parishes held on March 19th in the Mechanics' Institute, Torpoint, Mr. Charles Wm. Chubb, M.R.C.S. Eng., in recognition of his long connexion with the district, he having been in practice there for a period covering upwards of fifty years but having recently retired, was presented with a silver salver, a pair of silver candlesticks, and an illuminated address signed by all the subscribers representing the parishes of Torpoint, Antony, St. John's, and Wilcove. The salver and address were each appropriately inscribed.—On March 22nd, at Hamilton, Mr. J. Murray Young, M.B., M.S. Glasg., was presented at a social meeting of the members of the Livingstone Ambulance Class with a very handsome alabaster reading-lamp and shade in recognition of his services as instructor.—On March 16th, at St. Saviour's Infirmary, East Dulwich, Mr. H. Elwin Harris, B.A., M.B. Camb., F.R.C.S. Eng., medical superintendent, was presented by the staff of the above institution with a handsome gold watch and chain, suitably inscribed, on the occasion of his resigning his appointment. The Rev. G. Elliott, in presenting the testimonial on behalf, and in the presence of,

Hosted by Google

the whole of the staff of the infirmary, spoke in eulogistic terms of the many improvements which Dr. Harris had instituted during his five and a half years' tenure of office, laying special stress on his organisation and the method in which the nurses' training school was conducted, also the manner in which he championed the nurses' cause in the recent discussions on the Poor-law Superannuation Act.—At a public meeting held in Ferndale on March 24th Mr. S. Hamilton, B.A., M.B., B.Ch. R.U.I., was presented with an illuminated address, a marble mantel-piece clock, and a pair of bronze figures by the inhabitants as a mark of their appreciation of his services during his residence in Ferndale.—At a meeting at the Council Chambers, Municipal Buildings, Bournemouth, held on March 22nd, his Worship the Mayor presiding, Mr. Philip W. G. Nunn, L.R.C.P Lond., M.R.C.S. Eng., was presented with a cheque for £54 odd, subscribed by friends and patients as a mark of respect and esteem on his retirement from private practice in order to devote himself exclusively to his work as medical officer of the borough.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society, held on April 2nd, Dr. Thudichum being in the chair, Dr. Gossage gave a demonstration on the Serum Diagnosis of Typhoid Fever.—Dr. Harry Campbell read a paper on the Pathology and Treatment of Emphysema. He attributed the enlargement of the chest to diminution of pulmonary elasticity and consequently to diminished suction on the interior of the chest walls, also to chronic over-action of the inspiratory muscles in consequence of dyspnœa This caused contracture of the inspirators and fixation of the chest in the expanded position. Treatment should be directed to the preservation of pulmonary elasticity and to the strengthening of the expiratory muscles by means of special exercises so as to counteract the tendency to over-action of the inspirators.—Dr. Campbell Pope alluded to the occurrence of emphysema in muscular men with large chest capacity. Such men are frequently shallow breathers, the expansive muscles of respiration not being fully exercised. This predisposes to fixation of the rib-joints and ossification of the cartilages, the result being a large chest with little mobility, so that after an attack of bronchitis the less supported portion of the lungs—viz., the apices and margins—become emphysematous.—Dr. Thudichum dwelt on the importance of coughing as a cause of emphysema.

BEDFORD MEDICAL SOCIETY.—A meeting of this society was held on March 25th, Mr. Kinsey, the President, being in the chair.—The President gave an address on Medical Defence.—Dr. Goldsmith read notes of a severe case of Tetanus treated with antitoxin and morphia injections. The patient, a lad aged sixteen years, was first seen on Dec. 28th, 1896, with symptoms of tetanus. Two months previously he had cut a finger with a butcher's knife, and two weeks previously he had fallen on gravel and grazed his wrist, the latter probably being the origin of infection. On Dec. 29th 30 c.c. of Pasteur's fluid antitoxin serum, obtained from Messrs. Burroughs, Wellcome, and Co. were injected. On Dec. 30th 30 gr. of the solid serum, obtained from the British Institute of Preventive Medicine, were injected, and this was repeated the same evening and again on Dec. 31st. On Jan. 1st and 2nd 10 c.c. of the fluid serum (obtained from Messrs. Burroughs, Wellcome, and Co.) were given. He progressively got weaker and more emaciated until Jan. 6th, after which he gradually improved. Frequent injections of morphia were given from the commencement of the attack until the 17th, when the spasms had ceased and the patient was practically convalescent. Dr. Goldsmith was of opinion that the antitoxin had very little to do with the result, and that the injections of morphia were of the greatest benefit in checking the paroxysms.—Dr. Willmer Phillips read notes of a fatal case of Meningitis following an attack of Influenza and Pneumonia in a child aged two years, death occurring on the seventh day from commencement of influenza.—Mr. Nash read a paper on Inflammation of the Accessory Sinuses of the Nose and Ear, with special reference to several cases treated by free drainage.—The following specimens were shown: Adeno-carcinoma of the Rectum by the President; Tibia from a case of Acute Idiopathic Osteo-myelitis, which proved fatal in five days, by Dr. Ross; Excised Portions of the Knee-joint, Cystic Ovaries, Scirrhus of a Male Breast, a Gall-stone passed by Bowel after symptoms for three days of Intestinal Obstruction, and Skiagraphs of a Bullet in the Hand, by Mr. Nash

MEDICAL MAGISTRATES.—Dr. Reginald G. Alexander of Bradford and Dr. Robert Forsyth of Birstall, near Leeds, have been placed on the Commission of the Peace for the West Riding of the County of York.—Mr. Simeon Snell, F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S. Eng., and Mr. Alfred Wright, M.R.C.S. Eng., have been placed on the Commission of the Peace for the City of Sheffield and the County of Essex respectively.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 17th, Dr. W. B. Ransom, President, being in the chair.—Dr. Carroll read a paper on the Composition and Properties of Water, its Powers of Dissolving Gases and Minerals and thus breaking down rocks and forming soils. The causes of lead-poisoning in various places—e.g., Chesterfield rural district—were then indicated and the importance of other metals in solution shown. The law relating to water-supply was then briefly dealt with, the powers and duties of sanitary authorities under the various Acts, and the Dairies, &c., Order of 1885 being stated, and also the powers under the Rivers Pollution Prevention Act, 1876, to prevent the pollution of streams and other sources of water-supply. The substitutes for lead pipes were then reviewed. The intermittent and constant system of water-supply, the wholesomeness, the impurities, the hardness, and the purification of water were then gone into, and the importance of using bacteriological filters was shown. The softening of water by chemical means, and the enormous saving in soap, wear and tear of clothes, better cooking of food, repairs to boilers, and the use of less fuel, &c., were next alluded to, stress being laid on the facts that the harder the water the better it paid to soften it, and that the cost increased with the increase in the sulphates. By softening and subsequent filtration the water is practically sterilised. The analysis of water was next considered, the lecturer pointing out the danger of relying implicitly on a chemical analysis alone to prove the wholesomeness or otherwise of any particular water. The connexion between the use of polluted water and widespread outbreaks of enteric fever and cholera was next shown. In conclusion, the means of prevention of these diseases by destruction of the stools and other excreta by fire were advocated. It was pointed out that the present system of using disinfectants in the vessel to receive the excreta and emptying at once was simply a farce.—The President, Dr. Bolton, Mr. Littlewood, Dr. Hunter, and Dr. Mackenzie discussed the paper, and Dr. Carroll replied.

HARVEIAN SOCIETY.—A meeting of this society was held on April 1st, the President, Dr. Milson, being in the chair.—Mr. Buckston Browne read a paper on "Is it ever Impossible to Pass a Catheter through the Urethra into the Bladder?" He maintained that it was never impossible, even in the worst cases of stricture of the urethra, where the urethra had not in any part of its course actually ceased to exist, to pass an instrument. If an instrument was once passed the case could be brought to a successful issue without any perineal incision, and that being so the patient was saved all the risks of hæmorrhage and of that terrible misfortune, a perineal fistula. In the most severe cases of prostatic enlargement the urethra was simply tortuous. The difficulties were fully described and instruments were shown by which all these difficulties could be overcome. In no prostatic case was it allowed that the urethra was impassable by instruments, and therefore there was rarely any need for any form of prostatectomy or for castration. Other forms of urethral obstruction were discussed, and the question which was formulated in the title of the paper was answered emphatically in the negative.—Mr. Freyer remarked on the practical character of the paper. He was surprised to find that Mr. Browne had discarded soft for hard metal bougies in the treatment of strictures. He agreed that the knife was too frequently had recourse to in the treatment of stricture. He thought internal urethrotomy a safe and sound operation, but he believed external urethrotomy to be the only resource in other cases. He had never met with dangerous hæmorrhage in external urethrotomy, but sometimes a troublesome fistula remained. He also agreed that patient and cleanly catheterism was the best treatment for hypertrophy of the prostate.—Dr. Cock mentioned a case of intractable stricture in which he had drained the bladder above the pubes, and the patient led a comfortable life by wearing a tube and

Hosted by Google

spigot —Mr. Browne, in reply, said it was only in strictures, miscalled impassable, that he advocated the use of hard metal bougies.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Scotch Public Health Bill.

THE Bill of the Government to amend and consolidate the laws as to public health in Scotland has been read a second time in the House of Commons, and referred for consideration to the Grand Committee on Law. A proposal was made and largely supported to make the reference to a special committee consisting of all the representatives of Scotch constituencies, with fifteen members added by the Committee of Selection, but it was resisted by the Government, and on a division rejected by the House. This Bill was introduced last session in the House of Lords, where its details were closely examined and considerably altered by a Select Committee.

HOUSE OF COMMONS.

THURSDAY, APRIL 1ST.

The Plague in Bombay.

Sir Charles Cameron asked the Secretary of State for India whether his attention had been called to the systems of anti-plague inoculation which were being tried in India by M. Haffkine and Dr. Yersin, and the statement contained in a recent official despatch from Bombay that 3296 persons had already been inoculated by M. Haffkine; and whether, with a view of securing a prompt test of the protective and curative value of the procedures referred to, he would take steps to secure an independent official registration of all anti-plague inoculations, so as to enable the practical efficacy of the systems to be tested by subsequent comparison between the disease and death-rates among inoculated and non-inoculated persons.—Lord George Hamilton replied: I have been in frequent telegraphic correspondence with the Bombay Government regarding inoculations against plague. I have requested the Bombay Government to report periodically the number and the results of inoculations under M. Haffkine's and Dr. Yersin's systems separately.

FRIDAY, APRIL 2ND.

Military Hospital at Felixstowe.

Mr. Goddard asked the Under-Secretary of State for War whether the Army Sanitary Committee had made an inspection of the site for the proposed military hospital at Felixstowe, and whether he could give any information as to the site chosen.—Mr. Brodrick replied that the site approved by the Army Sanitary Committee for the proposed military hospital at Felixstowe was about 1000 yards north-east of Landguard Fort and 165 yards from high-water mark.

Lunacy Administration in Ireland.

Mr. Shee asked the Chief Secretary to the Lord-Lieutenant of Ireland whether, in view of the friction which had arisen between many of the boards of governors of Irish lunatic asylums and the Board of Control, he would take some steps, by legislation or otherwise, to amend or re-model the constitution of the Board of Control so as to render it directly representative of the ratepayers; whether he was aware that the Lunacy Commissioners in England acted in a similar capacity to the Irish Board of Control, but nevertheless claimed no power of veto such as the latter body claimed; and whether the governors of Irish lunatic asylums were allowed any discretion as to the extent and nature of the accommodation they might provide for inmates.—Mr. Gerald Balfour replied that the whole question of lunacy administration in Ireland was one requiring attention, though he could not promise that he should be able to deal with the matter in the immediate future. He was not sufficiently acquainted with lunacy administration in England to answer the second paragraph of the question. As regards the third paragraph, the fullest opportunity was uniformly afforded to local authorities to submit their views on any plans proposed for improved or increased accommodation, and these views received the most careful consideration of the Board of Control, with the utmost desire to adopt them so far as they might be found practicable.

Venereal Disease in the Army.

On the motion of Major Rasch a return was ordered of the amount of all classes of venereal disease (including simple venereal returns) for all stations where the Contagious Diseases Act was in force from 1864 to 1883, and a similar return for the same stations from 1886 to 1895.

MONDAY, APRIL 5TH.

Invalided Recruits.

Colonel Wyndham Murray asked the Under-Secretary of State for War whether his attention had been drawn to the fact, as shown in the Annual Report of Recruiting, that although the number of men under two years' service in the army was less last year than in any of the previous four years, yet the number of men under that length of service who were discharged as invalids was greater than in any of those years, and whether he could explain the reason for this increase of invalid recruits; and, with reference to the same report, whether he could state the reason why the numbers of militiamen who joined the regular forces had constantly diminished during the last five years, and whether the question of the reduction of the bounty given on completion of preliminary drill had been considered in connexion with this decrease.—Mr. Brodrick replied that there was a small increase in the invaliding of men under two years' service. It was probably attributable to the increased attention paid to physical training, by which men who were unable to bear the strain were more rapidly and surely found out. The diminution in the numbers of militiamen who had joined the regular forces might to some little extent be due to the reduction in the rate of bounty payable on completing their drill on enlistment. If it should continue to increase the question would be considered.

Irish Poor-law Relief Bill.

Mr. Gerald Balfour, in reply to Mr. McCartan, said it was not intended to appoint a committee to make inquiry into the working of the Poor-law system in Ireland in connexion with the Poor-law Relief Bill shortly to be introduced. It was hoped that the effect of the Bill would be to remove some of the difficulties standing in the way of classification and of other reforms.

TUESDAY, APRIL 6TH.

Health Lectures for Young Soldiers.

Colonel Wyndham Murray asked the Under Secretary of State for War whether he would consider the advisability of carrying out the recommendation of the Committee of the Royal College of Physicians contained in their report forwarded to the Secretary of State for India on March 29th, that medical officers of the army should give elementary reading-room lectures on the preservation of health to young soldiers; and whether these lectures could especially be given before or during their voyage to India.—Mr. Brodrick replied that the recommendation that medical officers of the army should give lectures to young soldiers on the preservation of their health was one to which great importance was attached, and the question of the time and manner in which such advice could be given was under consideration.

The London Water Question.

Mr. Sydney Buxton asked the President of the Local Government Board, with regard to that portion of the instructions to the Royal Commission on the London Water Companies which instructed them to inquire and report whether the financial considerations of the question rendered it desirable that the undertaking of the water companies should be acquired by a public authority or authorities, if he would state on what basis of purchase the Commissioners would be able to form an estimate of a fair price, whether it would be on the basis of proceedings under the Lands Clauses Act, under the so-called "Plunket" Clause, or under some other form of arbitration.—Mr. Chaplin said it appeared to him that it would be for the Commissioners to form such estimates as they might consider necessary for that purpose and to adopt such method or methods as they might deem desirable. They could, if they thought fit, form alternative estimates on different bases, but this was a question for them to decide.

WEDNESDAY, APRIL 7TH.

Local Officers Superannuation Bill.

Mr. Leuty asked the President of the Local Government Board whether he had taken any steps to ascertain the feeling of the local authorities of England and Wales as to the provisions of the Local Officers Superannuation Bill; and, if he had, would he inform the House with what result.—Mr. Chaplin replied that the Local Government Board had not taken any steps to ascertain the views of the local authorities in England and Wales as to the provisions of this Bill. There were many thousands of such authorities, and the Board had not seen any reason for adopting the unusual course of asking the authorities for their views as to the measure.

Institutions for Idiots and Imbeciles.

On the motion of Mr. Tomlinson a Bill was introduced and read a first time to exempt from poor and other local rates all registered institutions for the care, training, and education of idiots and imbeciles.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

AITKEN, J., M.B., C.M. Glasg., has been appointed Medical Officer by the Lancaster Board of Guardians.

BARTLETT, B. P., M.R.C.S., has been appointed Medical Officer for the Bourton Sanitary District of the Shaftesbury Union.

BATELY, JOHN, M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Belton Sanitary District of the Mutford and Lothingland Union.

BAYNES, Mr., has been re-appointed Public Analyst for the Borough of Hull.

BULLMORE, W. K., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Falmouth and Truro Port Sanitary Authority.

CALEY, H. A., M.C. Lond., M.R.C.P., has been appointed Lecturer on Materia Medica and Therapeutics in St. Mary's Hospital Medical School, vice Sidney Phillips, resigned.

COLLINGRIDGE, WM., M.D. Cantab., D.P.H., has been re-appointed Medical Officer of Health by the Port Sanitary Committee of the London Corporation.

CORSER, F. R. S., M.B., C.M. Edin., has been re-appointed Medical Officer for the Bourton-on-the-Water sub-Sanitary District.

CRERAR, CHAS., M.B., Ch. M. Edin., has been appointed Medical Officer for the Holme Abbey Sanitary District of Wigton Union.

DANIEL, R. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Chatteris Urban District Council.

DAVIDSON L. GORDON, M.B., Ch.M. Syd., has been re-appointed a Medical Officer to the Balmain Cottage Hospital, Sydney, New South Wales.

Hosted by Google

DUCAT, A. D., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for Chiswick, Middlesex.

DUNDAS, M. G., M.R.C.S., has been re-appointed Medical Officer for the Fanshaw Sanitary District by the Mitford and Launditch Rural District Council.

FAUSSET, H. J., M.D., M.Ch. Dubl., has been re-appointed Medical Officer of Health for the Tamworth Urban and Rural Sanitary Districts.

FISHER, F. C., F.R.C.S. Eng., has been re-appointed Medical Officer for the Abbott's Langley Sanitary District of the Watford Union.

GRAHAM, J. B., M.D., Ch.M. Irel., has been re-appointed an Honorary Medical Officer to the Balmain Cottage Hospital, Sydney, New South Wales.

HARRIS, D., M.B., C.M. Glasg., has been appointed Medical Officer and Public Vaccinator for the First Sanitary District and Workhouse of the Carmarthen Union, vice W. L. Hughes.

HOGARTH, A. L., M.B., C.M. Glasg., has been re-appointed a District Medical Officer by the Cheltenham Board of Guardians.

JAFFREY, FRANCIS, F.R.C.S. Eng., has been appointed Surgical Registrar to St. George's Hospital, London.

JONES, EDWARD, M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health for Dolgelly.

KELLY, P. J., M.B., Ch.H. Syd., has been re-appointed an Honorary Medical Officer to the Balmain Cottage Hospital, Sydney, New South Wales.

LIMRICK, W. S., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer by the Waterloo (Liverpool) District Council.

LYSTER, A. E., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Chelmsford Union, vice W. Hart.

MELSON, G. H., M.D. Lond., M.R.C.S., has been re-appointed an Honorary Physician to the Moseley Hall Convalescent Home for Children.

MILLER, J. T. R., L.R.C.P. Irel., has been re-appointed Medical Officer for the Leavening Sanitary District of the Malton Union.

MURPHY, D. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg. has been appointed Officer for the Youghal Workhouse, Cork.

NICHOLS, H. G., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Medical Officer to the Moseley Hall Convalescent Home for Children.

OWEN, ARTHUR DUNLEY, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer to the Mashonaland Mission Hospital, Fort Salisbury, Mashonaland, South Africa.

PALMER, A. M., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer by the Whittington Urban District Council.

PARKER, J. E., L.R.C.P. Irel., M.R.C.S., has been appointed Medical Officer for the Ince-in-Makerfield Sanitary District of the Wigan Union.

PEARCE, A., M.R.C.S., has been re-appointed Medical Officer by the Kingsbridge and Salcome Port Sanitary Authority.

PRIESTLEY, THOMAS, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Royal Hospital, Sheffield.

REYNOLDS, J. H., M.B., C.M. Edin., has been appointed Special Non-Resident Clinical Clerk to the Lock Wards, Royal Infirmary, Edinburgh.

RIDING, EDWIN, M.R.C.S., has been re-appointed Medical Officer of Health by the Rural District Council, Repton.

SMALLWOOD, R. P., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Eighth Sanitary District of the Chelmsford Union, vice E. P. Cockey.

SMITH, K. R., M.D. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Totnes.

TEMPLE, GEO. H., M.B., C.M. Edin., has been appointed Medical Officer for the Weston Super-Mare Sanitary District of the Axbridge Union.

TOTHILL, F. C., M.B., C.M. Edin., has been appointed Medical Officer for the Ashford Sanitary District of the Staines Union.

TUKE, G. M., M.R.C.S., has been re-appointed Medical Officer of Health by the Hollingbourne Rural District Council.

UNDERHILL, F. W., F.R.C.S. Edin., M.R.C.S., has been re-appointed an Honorary Medical Officer to the Moseley Hall Convalescent Home for Children.

WILSON, J., M.D., C.M. Edin., has been re-appointed a District Medical Officer by the Cheltenham Board of Guardians.

YOUNG, MEREDITH, M.B., C.M. Edin., D.P.H. Vict., has been appointed Medical Officer of Health for the Borough of Crewe.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BOROUGH OF BRIGHOUSE.—Medical Officer of Health for the Borough. Salary £200 per annum. Applications to the Town Clerk, Town Clerk's Office, Brighouse.

BRENTFORD UNION.—Dispenser for the Infirmary Workhouse and Schools at Isleworth. Salary £100 per annum, with dinner and tea daily.—Applications to the Clerk, Union Offices, Isleworth, Middlesex.

BRITISH LYING-IN HOSPITAL, Endell-street, Long-acre, W.C.—Administrator of Anæsthetics.

BURY DISPENSARY HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, residence, and attendance.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY, Wakefield.—House Surgeon, unmarried. Salary £90 per annum, with board, lodging, and washing.

COMBINED DISTRICT OF BATTLE, CUCKFIELD, EASTBOURNE, &c.—Medical Officer of Health, for three years. Salary £600 per annum, to include all travelling and other expenses. Applications to the Secretary, Haywards Heath.

DUNDEE ROYAL INFIRMARY.—Second Honorary Assistant Physician.

GENERAL INFIRMARY, Leeds.—Resident Surgical Officer. Salary £100 per annum, with board, residence, and washing.

GERMAN HOSPITAL, Dalston, N.E.—Honorary Ophthalmic Surgeon.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six months. Board, lodging, and washing in hospital provided.

HANTS COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance. Applications to the Committee of Visitors, Knowle, Fareham.

HOSPITAL FOR WOMEN AND CHILDREN, Leeds.—House Surgeon for twelve months. Salary £90 per annum.

LIVERPOOL NORTHERN HOSPITAL.—Honorary Physician.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £80, to be increased to £90 per annum after the first year's service, with apartments, board, and attendance. Applications to the Secretary, 34, Moorfields, Liverpool.

NEW SOUTH WALES.—Bacteriologist and Assistant to the President of the Board of Health of the Colony. Salary £600 per annum. Applications to Agent-General for New South Wales, 9, Victoria-street, London, S.W.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and Assistant Resident Medical Officer, for six months. A salary at the rate of £50 per annum for the senior post.

NOTTINGHAM GENERAL DISPENSARY.—Junior Assistant Resident Surgeon, for six months. Salary at the rate of £120 per annum, with rooms and attendance.

PARISH OF ROUSAY AND EGILSHAY, Orkney.—Medical Officer. Salary £51 sterling per annum. Applications to the Clerk of Parish Council, Rousay, Orkney.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Examiners.

SEAMEN'S HOSPITAL SOCIETY (Dreadnought), Greenwich, S.E.—House-Physician. Salary £75 per annum, with board and residence.

ST. SAVIOUR'S UNION, Surrey.—Medical Superintendent at the Infirmary, East Dulwich-grove, S.E. Salary at the rate of £400 per annum, with unfurnished house, coals, gas, and water. An annual percentage deduction from the salary and emoluments will be made according to the Poor-law Officers Superannuation Act, 1896. Applications to the Clerk, Union Offices, John-street West, Blackfriars-road, S.E.

SHEFFIELD GENERAL INFIRMARY.—Junior Assistant House Surgeon, for three years. Salary £50 per annum, with board, lodging, and washing.

TAUNTON AND SOMERSET HOSPITAL, TAUNTON.—Assistant House-Surgeon for six months. Board, washing, and lodging in the institution provided.

UNIVERSITY COLLEGE, Bristol.—Medical Tutor. Stipend £125 per annum.

WESTMINSTER GENERAL INFIRMARY, Gerrard-street, Soho, W.—Resident Medical Officer, for one year.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon, for six months. Salary at the rate of £70 per annum, with rooms, board, and washing.

WONFORD HOUSE HOSPITAL FOR THE INSANE, near Exeter.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, and washing.

Births, Marriages, and Deaths.

BIRTHS.

EMMETT.—On April 2nd, at Woodville, Kingston-road, Portsmouth, the wife of Richard Emmett, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MCKENZIE.—On March 12th, at Glenlyon, Berea, Durban, Natal, the wife of Dr. Archibald McKenzie, of a daughter.

THOMSON.—On April 1st, at Elleray, The Avenue, Ealing, W., the wife of George Thomson, M.B., of a daughter.

MARRIAGES.

BERNHARDT—FLACK.—On April 3rd, at Christ Church, Brondesbury, Dudley Richard Bernhardt, M.R.C.S., L.R.C.P., L.S.A., of Hamilton-terrace, W., to Beatrice Mary Flack, of South Mansions, Streatley-road, Brondesbury, fourth daughter of the late Horace Flack.

EYRE—LEWIS.—On March 31st, at the Parish Church, Folkestone, Surgeon-Lieut.-Colonel Montague Stokes Eyre, I.M.S., second son of the late Surgeon-General Eyre, to Emily Frances, eldest daughter of Henry Lewis, M.D., Folkestone.

DEATHS.

GARDNER.—On April 1st, at Naples, William Gardner, M.D. Glasg., of Melbourne, Victoria.

REILLY.—On March 30th, in London, Edwin James Reilly, M.R.C.S., L.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (14th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (15th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (17th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (12th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Mr. R. Harrison (President): Case of Extrophy of the Bladder with Epispadias, treated by Left Nephrectomy and Right Ureteral Transplantation.—Mr. Turner (for Dr. Rolleston): (1) Case of Spastic Hemiplegia after Whooping Cough; (2) Case of Acromegaly.—Mr. Battle: (1) Result of Operation for Excessive Deformity of Lower Extremities; (2) Amputation of Thumb for Large Sarcomatous Growth in a Man the subject of Multiple Bony Growths; (3) Dislocation of Head of Radius from Ulna due to Rupture of Orbicular Ligament; (4) Early Condition of Baker's Cyst of Knee.—Dr. L. Guthrie: Multiple Spontaneous Fractures in an Infant.—Mr. Turner: Case of Lymphangioma.

TUESDAY (13th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8 30 P.M. Mr. R. L. Knaggs: Compound Depressed Fracture of the Skull, Cerebral Abscess. Hernia Cerebri, Recovery, with a consideration of the subject of Hernia Cerebri based upon 109 collected cases.—Dr. J. W. Carr: Non-Tubercular Posterior Basic Meningitis in Infants.

WEDNESDAY (14th).—HUNTERIAN SOCIETY.—Clinical Evening. Cases will be shown by Mr. H. Grant, Mr. J. H. Sequeira, Mr. T. H. Openshaw, Mr. H. V. Hickman, Dr. Woods, and Dr. F. J. Smith.

SOUTH-WEST LONDON MEDICAL SOCIETY (Stanley's, 235, Lavender-hill).—8.30 P.M. Paper:—Dr. C. Smith: Etiology of Diphtheria, with special reference to two localised outbreaks in Wandsworth. Dr. Sims Woodhead will give a Limelight and Microscopic Demonstration of the Diphtheria Bacilli.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. Pegler, Dr. H. L. Lack, Mr. de Santi, Dr. A. Bronner, Dr. F. de H. Hall, Dr. F. Potter, Dr. S. Spicer, Dr. W. Hill, and Dr. Bennett.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (12th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Dr. G. Reid: Sanitary Appliances.

WEDNESDAY (14th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Mr. O. Fleming (conducted by): Inspection and Demonstration of Artisans' Dwellings, Boundary Street Area, Bethnal Green.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"SAFE LAMPS."

THE Moonlight Patent Lamp Company, Limited, of 126, Paddington Liverpool, have submitted to us for inspection a model of their night lamp. The essential principle of this lamp is that the reservoir never contains an excess of oil; that is, instead of filling the reservoir with oil in the usual way it is only necessary to saturate the absorbent with which it is charged. There is therefore no room for explosion in the reservoir, the space being occupied by the absorbent. The lamp is well adapted for burning benzoline, the cost of its employment as a nightlight being, it is stated, only a penny a night. A decided advantage is that the wick does not char and consequently very seldom requires adjusting. It gives a clear, white, steady flame which is entirely without smell. The same principle is applied to cycle lamps, carriage lamps, &c., all of which give an excellent degree of illuminating power.

MR. J. H. LAPTHORN, of 361A, Oxford-street, Manchester, sends us two lamps which provide against the ordinary disadvantages of the reservoir being constructed of glass on the one hand and of metal on the other. The main objection to glass is that it is fragile and liable to crack with alternations of temperature, but one advantage it presents is that the amount of oil in the reservoir may be seen. The disadvantage he proposes to overcome by placing the reservoir in a strong basket of wire after the manner of a "seltzogene," while the disadvantage of a metal reservoir—that is, its opacity—he proposes to remedy by placing a small ballcock in the reservoir, which would show by means of an indicator outside the quantity of oil contained in the reservoir. Neither device appeals to us as offering any satisfactory solution of the problem of lamp construction; we have seen much simpler designs which are more reliable and more convenient.

MR. W. MACADAM, of 7, Latchmere-street, Battersea-park-road, has submitted to us a drawing of a safety lamp which he proposes to construct. It contains a wick tube running to the base of the reservior and terminating in a small box containing a spherical plug. When the lamp is in an upright position the oil is free to flow through the wick tube, but should the lamp be upset in any direction the spherical plug blocks the wick tube and prevents the escape of oil. This method may be applied to the duplex lamp also. In addition, it is practically impossible for an explosion to take place since the air space is quite cut off from communication with the flame. The design is simple and we should say fulfils the requirements of a lamp that can correctly be called safe.

Dr. S.—If our correspondent can prove what he says he would have grounds for demanding an explanation and probably would be well advised in seeking one. But he must not rely too much on the accuracy of the patients.

DR. CALMETTE'S ANTI-VENOMOUS SERUM.

DR. HAZARD, of the French Colonial Service, reports (*Archives de Médecine Navale et Coloniale*, March, 1897) a case of recovery from snake bite after injection of Dr. Calmette's anti-venomous serum. In December last at Martinique a soldier, aged twenty-three years, was bitten in the left thumb by a vigorous trigonocephalus (Bothrops Lanceolatus), nearly five feet in length. When the accident occurred the man was in a squatting position, but although he instantly jumped to his feet the action failed to dislodge the reptile, which remained for some moments firmly fixed to his digit, and it was not until he struck it on the head with his fist that it relaxed its grip and fell to the ground. There were two punctured wounds about half an inch apart, one of which was bleeding slightly. With a penknife the soldier enlarged it superficially, and he sucked the place three or four times. An officer then bound a ligature tightly round the root of the thumb, and dispatched the man to the hospital, where he arrived breathless from running some ten or twelve minutes after receiving the bite. To save time he was attended to in the office. Ten cubic centimetres of anti-venomous serum (which had been received from Lille in the course of the preceding month) were subcutaneously injected into the patient's left flank. The seat of injury was washed with hypochlorite of lime, and five cubic centimetres of the latter solution having been injected into and around the punctures the constricting ligature was removed. Soon afterwards the principal medical officer arrived at the hospital, and the case being in his opinion very grave he ordered a second injection of 10 cubic centimetres of serum, as well as a second local injection of 4 cubic centimetres of the hypochlorite. The patient was then put to bed under several blankets and given strong coffee to drink at frequent intervals. For forty-eight hours he complained of darting pains in his arm, loss of appetite, and sleeplessness—the last symptoms being no doubt due to the coffee—but with these exceptions the indications were entirely favourable. There was no local tumefaction, and the axillary glands remained unenlarged. On the fifth day the man had perfectly recovered and was discharged to duty. Immediately after he was bitten he says his forearm became heavy and numb, as though it were asleep, and neither the incision he made himself nor the hypochlorite injections caused him the least pain. This anæsthesia only lasted a few hours, the sense of feeling being fully restored by the next morning.

Viator.—The right course to be taken is to approach the local sanitary authority. When this has been done, and to no purpose, we might try to be of use, but the properly appointed officer must first be found wanting.

QUACKS AND THEIR WAYS.

To the Editors of THE LANCET.

SIRS,—I beg to enclose a letter which was sent to a patient of mine, whose name I will ask you to suppress. The patient is an advanced general paralytic. I am, Sirs, yours faithfully,

Brackley House, Newmarket, April 6th, 1897. JOHN H. MAUND.

[ENCLOSURE.]

March 30th, 1897, 54, Watkinson-street, Liverpool.

Mr.——I wrote to you yesterday, but I understand that the doctors will not allow you to try my cure. If you will send for me to come to you I will certainly give you such relief that will result in a return to perfect health. I await your reply. TIMOTHY NARY.

Mr. J. T. Clare (Straits Settlements).—The communication has been forwarded to the patentees of the apparatus mentioned.

M.D. (Chiswick) would like to hear of an institute or home where a girl aged eight years, could be received. She is now in a Poor-law infirmary, but the board of guardians would pay from 7*s.* to 10*s.* per week for her maintenance. She suffers from a mild form of idiocy and has a slight epileptic fit about once a month; occasionally she has a more severe fit. She frequently has incontinence of urine at night. Her general health is good.

THE PROPOSED NATIONAL PROVINCIAL CRIPPLES AID UNION.

MR. GILLINGHAM of Chard, whose scheme we noticed in THE LANCET of Feb. 13th, sends us a long letter on the same subject. He draws attention to the fact that though the London aid societies are doing good work in aiding cripples, still this presses very hardly on provincial mechanicians, who are in many cases quite equal to making the necessary appliances. But as the London societies are under contract to metropolitan firms these latter always get the orders. We are afraid that this is not the only instance where the provinces are deprived of their due by the octopus of London. The same holds good as regards metropolitan hospitals, and we quite agree with Mr Gillingham's argument that if the proposed union were arranged it would not only be a benefit to many cripples by bringing aid to their doors, but would also bring about an increase of trade to provincial mechanicians.

A RELATION OF EDWARD JENNER.

A CORRESPONDENT has called our attention to the fact, with reference to the Jenner Memorial Celebration, that a relation of Edward Jenner—a second cousin—is still living in the person of the Rev. Edward Henry Lane Noott, vicar of St. John's, Dudley, and now in his eighty-first year. Mr. Noott's mother, whose maiden name was Miss Mary Higgon, was a first cousin to Dr. Edward Jenner and was vaccinated by him personally.

Enquirer is placed in a somewhat awkward position by the case he describes. There is no greater kindness in the heads of houses than to act with consideration to their servants when they fall sick, especially with a grave and infectious disease like scarlet fever, as in this case. But the kindness to be complete must extend till all desquamation is over. Here—naturally, no doubt—the lady has become impatient. It is certainly desirable that where a case of scarlet fever arises there it should remain, saving always removal to an isolation hospital provided in the district for such cases. Is there any reason why the lady and family should not return to her house? We assume that the patient and nurse have been kept to one or two rooms. As to removal to a distance of six miles, this can be done, no doubt, and with due precautions need not involve any violation of the Public Health Acts; but the course is very objectionable. Without a proper ambulance and trained persons to carry out the removal there will be a great probability of carrying infection to a new district, and such action might involve the good relations of the patient's father with his employer. We scarcely think that any action would lie on the ground of such removal, if due care against exposure of the patient or his clothes is observed and the carriage in which he is conveyed is thoroughly disinfected. The objecting parties have no legal power to prevent the boy going to his own home; but it is highly desirable that the case should remain where it is till all trace of desquamation is over. If this cannot be, some amicable arrangement must be sought for by which the shepherd may be kept apart from the desquamating patient till all risk is over.

THE ENTERPRISE OF AN L.O.S.

To the Editors of THE LANCET.

SIRS,—Thinking the enclosed might be interesting to the profession as indicating what we may expect in the near future, I have cut it from the advertisement columns of one of our local papers.

I remain, Sirs, yours truly,

EDWARD LYNN, M.R.C.S. Eng., L.S.A. Lond.

New Charlton, April 5th, 1897.

[ENCLOSURE.]

MIDWIFERY AND DISEASES OF WOMEN AND CHILDREN.
MRS. HOBBS, L.O.S.,

Trained at, and afterwards on the Staff of, Queen Charlotte's Hospital, may be consulted at 81, Lee High-road, Lewisham, either personally or by letter. A full stock of Drugs, Chemicals, and Herbs kept constantly on hand.

Diplomas, Certificates, and Testimonials may be seen on application.

—*Kentish Mercury*, April 2nd, 1897.

F. V.—There is no book that we know of dealing with French watering places exactly as our correspondent requires. The most suitable for his purpose would be one of the "Guides Joanne" which deals with the Normandy coast, to be procured from Hachette et Cie. or through any bookseller. Etretat, Trouville, St. Addresse, Berck-sur-Mer, and Wimereux are all well-known places on the north coast, and further south there are Biarritz and St. Jean de Luz, as well as the Riviera resorts, which it is unnecessary to particularise. The sanitation of Boulogne has improved immensely of late years. It has a main drainage system, with which all houses are obliged to be connected, and a good water-supply. A correspondent who has exceptional sources of information says that during four whole years and three summers of three other years he saw only one case of diphtheria and three of typhoid fever there, one of the latter being imported.

A READY RETORT.

OUR contemporary the *Guyoscope*, whose April issue has the same meritorious quality of lively good humour that marked its former numbers, is responsible for the following:—

> A gentleman, not unknown to fame, had left his corner seat in the already crowded carriage to go in search of buns and milk, or cake and sherry, leaving a rug to reserve his seat. On returning he found that, in spite of the rug and protests of his fellow-passengers, the seat had been usurped by one in lady's garments. To his protestations her lofty reply was: "Do you know, sir, that I am one of the director's wives!" "Madam," he replied, "were you the director's only wife, I should still protest."

THE Worshipful Company of Skinners have sent a donation of ten guineas to the Royal Hospital for Diseases of the Chest, City-road.

Hosted by Google

CHICAGO VITAL STATISTICS.

THE report of the Bureau of Vital Statistics of Chicago for February, 1897, contains a large number of interesting details of the disease and mortality of that wonderful city, with its population of 1,619,226. But what seems a new feature in it is a circular for distribution, either generally or among families affected with infectious complaints. The circular, we are told, has been written at the request of physicians who have not time to write in sufficient detail and with necessary precision instructions for the restriction and destruction of contagion. The idea is a good one, and might be more extensively adopted among ourselves with advantage. We cannot refrain from giving the following particulars of antitoxin diphtheria treatment, verified by the name of Dr. E. P. Murdoch, chief of the antitoxin staff:—

No. of cases visited	... ...	152
,,	bacterially verified as true diphtheria ...	81
,,	treated with antitoxin	81
,,	recovered	72
,,	died	5
,,	remaining under treatment	4
,,	treated with immunising doses	40
,,	treated with immunising doses subsequently attacked with diphtheria	0
,,	intubated	8
,,	intubated which recovered	7

Exclusive of 4 cases remaining under treatment at the end of the month, the mortality rate was 6·4 per cent. of bacterially verified diphtheria—72 recoveries, 5 deaths. Out of a total of 1772 deaths, 31 were caused by puerperal septicæmia.

Delta.—There is nothing unprofessional in informing patients of an intended change of address, but our correspondent must be very careful only to inform *his* patients. No circulars should be sent broad-cast to the public, and advertisements in local papers are inadvisable.

"MATERNAL IMPRESSION ON THE FŒTUS."

To the Editors of THE LANCET.

SIRS,—Many medical men believe in maternal impressions on the fœtus, and personally I do, from nearly twenty-nine years of midwifery practice in which I have seen some remarkable cases. Puppies brought up under the influence of red light are said to grow up irritable and pugnacious, and those exposed to a green or blue light to turn out good-tempered. Carry out the same surroundings with a bitch or any other animal during the whole time, or at all events the early part, of pregnancy, and carefully test the results in a number of the young animals for a year or two succeeding birth. Other experiments of a somewhat different nature could then be tried, and if the conclusions arrived at pointed to a distinct effect being produced on the fœtus through the mother's perception it would go a good way to prove that a branch of science in relation to the human mother has not received the attention which is due to it.

I am, Sirs, yours faithfully,

March 29th, 1897. ANOTHER M.R.C.S., L.S.A.

Mr. C. E. Abbott.—In our opinion the responsibility devolved on B., as the infant had developed an entirely new complaint since A. had seen him last.

Dr. A. P. de Andrade does not appear to us to make out a very good case for the proposed innovation.

THE PROVINCE OF THE OPTICIAN.

WE have received from Mr. Frank Howard a second communication concerning our notice of his circular, which he says amounts to a libel. We confess our inability to see the matter in the same light. Mr. Frank Howard is not an ophthalmic surgeon, and in making an offer to the profession to diagnose surgical cases and to recommend appropriate treatment he seems to us to have exceeded his province. Mr. Howard sees in our treatment of his communication last week an aggravation of our offending and a proof of malice, but there he does us no justice. If he will glance at our columns he will see (1) that a discussion on any subject in THE LANCET is *always* continued under its original heading, and (2) that the type used for the headings to editorial paragraphs is *always* smaller than that used for the headings to letters from correspondents. This is our invariable rule, which we break on this occasion. The following letter requires an explanation from Mr. Howard to be given to all the medical men who have received his circular:—

To the Editors of THE LANCET.

SIRS,—I am directed by the Committee of the Central London Ophthalmic Hospital to state, in reference to some correspondence under the heading "An Insolent Advertisement," that the only opticians officially recognised by this institution are the firm of Messrs. Curry and Paxton.

I am, Sirs, yours faithfully,

Central London Ophthalmic Hospital, J. G. BRYANT,
Gray's-inn-road, W.C., April 6th, 1897. Secretary.

RADIOGRAPHIC DERMATITIS.

To the Editors of THE LANCET.

SIRS,—I am much interested in your annotation on "Radiographic Dermatitis with Ostitis." I have been working on the x rays for over twelve months; during that time my hands and arms must have been exposed to the rays for many hours, sometimes for several hours at a time, when making experiments with new tubes and apparatus. I will premise that I have an exceedingly sensitive skin, so much so that when I spend a week under canvas with the Volunteers I invariably have severe erysipelatous inflammation of the skin of the face and have often been almost blind for two or three days. My hands, also, will blister directly if exposed to the direct rays of the sun for any length of time. In spite of this I have never noticed the faintest trace of any inflammation or bronzing due to the x rays, nor have I ever seen any signs of irritation of the skin in any of my patients. I have had many prolonged exposures of children with delicate skins, frequently with the skin entirely unprotected by clothing, &c.

In view of your suggestion as to the *luminous* rays, it will interest you to know that I perform all my experiments with the entire apparatus enclosed in a large, light-tight box with cardboard doors, so that no luminous rays can penetrate. Is it not also possible that the signs of ostitis in Mr. Gilchrist's case may be due to the puffy inflammation of the skin? I have frequently noticed that on examination of, say, a hand when the soft tissues are inflamed, as in cellulitis, one finds an apparent thickening of the bone, really due to the swollen soft tissues preventing close contact of the bone with the sensitive plate. Even a fraction of an inch will give an apparent enlargement. The loss of detail in the bone would also be due to the same cause. I find I have to be constantly on my guard to avoid these skiagraphic fallacies.

I am, Sirs, yours faithfully,

Northwich, March 30th, 1897. ALF. H. MARSH, L.S.A.

L. D. T.—Our correspondent is quite right with regard to the insanitary nature of both methods of procedure. But he is wrong in thinking that they pass unnoticed, for much has been done in the past and continues to be done in the present to put a stop to them.

H. R.—"A Guide to the Examination of the Urine," by J. Wickham Legg, M.D., F.R.C.P. Lond. (London: H. K. Lewis), price 3*s.* 6*d.*; and "Notes on Examination of Blood and Excreta," by Sidney Coupland, M.D., F.R.C.P. Lond. (H. K. Lewis), price 1*s.* 6*d.*

H. B.—We cannot vouch for the facts, but some years ago it was commonly reported that a corpse was preserved on the top of a house in the West-end of London. It was said to be embalmed and placed in a glass coffin.

Paine.—A death from hydrophobia was recorded in THE LANCET of July 25th, 1896, p. 256. It occurred at Radcliffe about ten days previously. The victim had been bitten by a mad dog in the preceding November.

M.R.C.S.—Nothing has yet been decided about reproductions, but there is to be a meeting of the committee of subscribers on Friday, the 9th, when the matter will be discussed.

An Old Subscriber is requested to supplement his information from the Central Criminal Court by giving us his name and address—of course, in strict confidence.

ERRATUM.—In our notice in THE LANCET of April 3rd, p. 965, of Mack's Austrian Pine Products, the word "soluble" should have been inserted before the word "essence" in the sixth line, and instead of "colourless oil" in the succeeding line it should read "colourless *liquid*." The essential oil itself boils at between 330° and 350° F.

During the week marked copies of the following newspapers have been received:—*Bath Herald, Daily Mail, Hull News, Folkestone Express, Evesham Journal, Derbyshire Times, Bury Free Press, South Durham Mercury, Bournemouth Directory, Times of India, Bedfordshire Independent, Pioneer Mail, Leicester Post, Bradford Observer, Manchester Courier, Newcastle Journal, Builder, Dundee Courier, East Anglian Weekly Times, South Wales Daily News, Architect, Liverpool Daily Post, Scotsman, Citizen, Norwich Mercury, Grantham Journal, Hastings Observer, Yorkshire Post, Hereford Times, Bristol Mercury, Sussex Daily News, Portsmouth Times, Leeds Mercury, Wolverhampton Chronicle, Midland Counties Express, Worcester Echo, Sheffield Telegraph, West Kent Advertiser, Bexhill-on-Sea Observer, Chatham News, South-Eastern Gazette, Somerset Herald, Andover Advertiser, Surrey Comet, Acton Gazette, North British Daily Mail, Worcestershire Chronicle, Sketch, City Press, Birmingham Post, Sanitary Record, Cayuga County Independent, Auburn, N.Y., Reading Mercury, Crewe Chronicle, Mining Journal, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Hertfordshire Mercury, Shetland News, Surrey Advertiser, Local Government Journal, Public Health, Devizes Gazette, Aldershot News, Wigan Observer, Poole Herald, Wrexham Argus, Witney Gazette, West Middlesex Herald, South Western Gazette, National Press Journal, &c., &c.*

The Photographic Art

AS AN AID TO MEDICAL AND SURGICAL SCIENCE.

The utility of photography as an aid to medical and surgical science is so obvious that it is a matter of surprise that its use has been hitherto, comparatively speaking, restricted. As a means whereby clinical results and microscopical researches may be permanently recorded, photography is far more accurate than any drawing can hope to be, and in the hands of the careful worker is capable of producing important results. The successful application of the x rays to surgical diagnosis has undoubtedly acted as a great stimulus to the adoption by medical men of the longer known but somewhat neglected art. Again, the camera naturally appeals to the medical man as a means of relaxation and a scientific hobby after his own heart. In any case the introduction of Photographic "Tabloids" has done much to render the manipulation of plates and prints a matter of much greater ease than hitherto. In the past the great drawbacks, especially to the busy physician or surgeon, have been the time and trouble required to prepare the necessary solutions, and their liability to decompose and become uncertain in composition and action when prepared at home or purchased ready made.

The Photographic "Tabloid" disposes of every previous objection. Each "Tabloid" contains in a compressed and soluble form, a definite quantity of photographic chemical. No weighing is required, and uniform results are obtained. There is no danger of deterioration as in the case of stock solutions, as the "tabloid" is dissolved only when required, and furnishes a fresh and active solution for immediate use.

A medical officer writing from Lake Tanganyika, British Central Africa, says: "I always use your 'tabloids' in photography; they are most excellent in every way, uniform in strength, cleanly, inexpensive, and everything to commend them. I have tried all sorts of developers, but none equal your 'tabloids.'"

Photographic "tabloids" occupy very little space, an important point when travelling, and have the additional advantage of being free from the tendency shown by fluids to do irretrievable damage to the other contents of the knapsack should accidental leakage or breakage occur.

PHOTOGRAPHIC "TABLOID" LIST.

Developing "Tabloids":—

Eikonogen, Eikonogen with Quinol; Paramidophenol; Pyro-Developer; Pure Pyrogallic Acid, 1, 2, and 4 grs.; Quinol (Hydroquinone); Pyrogallic Acid with Eikonogen; Quinol with Pyrogallic Acid.

Accelerator "Tabloids."

Restrainer "Tabloids":—

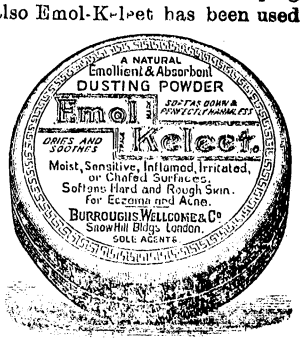
Potassium Bromide, 1 gr.; Ammonium Bromide, 1 gr.
In large and small bottles, 5d. and 9d. per bottle.

Toning "Tabloids":—

Toning Gold Compound, *in tubes at 8d. each.*

"SAXIN TABLOIDS."

"Saxin" has been aptly termed "the sweetest thing on earth," being about 600 times sweeter than sugar. It is perfectly harmless, as it undergoes no change in its passage through the digestive system, but simply imparts its delicate sweet flavour to the food or fluid with which it is used. For these reasons it is indicated in such conditions of disease as diabetes mellitus, gout, obesity, glycosuria, &c., in which the patient is debarred from taking sugar and yet retains an intense desire for the sweet flavour to which the palate has by long use become accustomed.



"Saxin" has important qualities which render it superior to other sweetening substances. It is unfermentable and permanent. It operates antiseptically, and prevents decomposition. In flavour it is more delicate than any other sweetening agent, and, in the shape of "Saxin Tabloids," ¼ gr. each, it provides the maximum amount of sweetening power in the smallest possible space. A small bottle, containing 100 or 200 "tabloids," can be carried in the vest pocket without the slightest inconvenience, and thus the patient who must avoid sugar can have a delicately flavoured, harmless sweetening agent always handy when at business or when travelling at home or abroad.

"Saxin Tabloids," ¼ gr., are each equivalent to one lump of best loaf sugar, and are supplied in bottles of 100 and 200 "tabloids," at 7d. and 1s. 1d. per bottle.

EMOL-KELEET.

Emol-Keleet is a natural mineral powder carefully purified but unsophisticated in any way. It has been largely used by physicians as a dusting powder in the treatment of cutaneous diseases, and for allaying irritation such as occurs in urticaria, the eruptive period of measles, &c. In moist or weeping conditions of the epidermis also Emol-Keleet has been used with most beneficial effects, and has further attracted attention owing to its wonderful softening influence upon the horny accretions of keratosis and other hardened conditions of the skin.

A recent report in the BRITISH MEDICAL JOURNAL (March 13th, 1897) by the lecturer on Pharmacology at Westminster Hospital points out the dangerous adulteration that is carried on in the case of many toilet powders, such minerals as zinc, bismuth, and lead being present in some samples to the extent of 40 per cent.

The effect of such powders on the delicate skins of infants may be readily recognised, and it is suggested that the physician guards against their use in the nursery.

By chemical analysis and extended therapeutic trial, Emol-Keleet has been proved to be a pure, emollient, natural mineral powder, possessing marked soothing and healing properties.

Emol-Keleet is supplied to the profession in boxes at 9d. each.

SOME OPINIONS OF EXPERTS AS TO THE VALUE OF

TAKA-DIASTASE

AS AN AID TO DIGESTION.

"Hitherto the digestive properties of diastase have been appropriated chiefly by using active extracts of malt, which, of course, contain a large excess of malt sugar, which in certain cases it is desirable to exclude. The use of the Taka-Diastase, therefore, offers obvious advantages on this head."—THE LANCET, May 25th, 1895.

"There is no doubt ..... that in Taka-Diastase we have an exceedingly powerful starch ferment which will give us results more certain than those we have hitherto learnt to be thankful for."—QUARTERLY MEDICAL JOURNAL, January, 1896.

"It is capable of converting over one hundred times its weight of starch into sugar, and it must, therefore, be a valuable drug in the treatment of amylaceous dyspepsia."—BRISTOL MED. CHIR. JOURNAL, September, 1896.

"It seems to be established that flatulent dyspepsia is most commonly caused by faulty starch digestion, in which case we should expect benefit to follow the ingestion of this ferment. Such, we find, occurs in practice, with the further advantage that the constipation which almost always accompanies this form of dyspepsia is rapidly relieved at the same time."—QUARTERLY MEDICAL JOURNAL, April, 1897.

"We have carried out a series of tests with the Taka-Diastase, comparing it with three of the best-known malt extracts; also with a sample of commercial diastase in powder. The result of these experiments showed that Taka-Diastase was, weight for weight, sixty times the diastasic strength of the malt extracts, and that the commercial diastase had no starch-converting power at all."—CLINICAL SKETCHES, November, 1895.

"It is evident that in this product we have a medicinal agent for which there should be a place in therapeutics."—CHEMIST AND DRUGGIST, Jan. 25th, 1896.

"The question of the dependance of many forms of dyspepsia on the presence of undigested starch in the stomach is one which is not so fully recognised by all practitioners as it should be, and we can recommend any of our readers who expect such to be the nature of some cases of intractable dyspepsia to try the effect of Taka-Diastase. We also venture to suggest its use in the feeding of infants, in whom the dire effects of starchy foods and their influence on rickets is well known."—WEST LONDON MEDICAL JOURNAL, January, 1896.

"The new ferment promises to become a remedy for amylaceous indigestion. ..... It has passed the experimental stage, and many excellent reports have been made from physicians of repute on its value."—SCALPEL, February, 1896.

"Taka-Diastase is, as we have found by experiment, an exceedingly active form of diastase..... In reducing carbohydrates to a soluble and probably more assimilable condition in food it should prove of great service."—THE LANCET, March 28th, 1896.

"I am convinced that in Taka-Diastase we have at command a remedy of the highest value, which is capable of giving excellent results in many obstinate cases of dyspepsia, auto-poisoning with amylon-ptomaines, and the resulting train of symptoms so frequently classed together under the names of latent and suppressed gout."—W. ARMSTRONG, Esq., M.R.C.S., in LIVERPOOL MEDICO-CHIRURGICAL JOURNAL, January, 1897.

The Goulstonian Lectures

ON

THE CHEMISTRY AND PATHOLOGY OF GOUT.

Delivered before the Royal College of Physicians of London,

BY ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS IN ST. MARY'S HOSPITAL, AND LECTURER ON FORENSIC MEDICINE IN ST. MARY'S HOSPITAL MEDICAL SCHOOL.

LECTURE III.[1]

Delivered on March 30th.

CAUSES AFFECTING THE DEPOSITION OF SODIUM BIURATE.

Deposition encouraged by concentration of medium and proportions of sodium salts present.—Sir William Roberts found that sodium biurate is very sparingly soluble in blood serum; at blood heat the amount dissolved is about 1 part in 10,000 (about one-tenth of its solubility in water). This lessened solubility is entirely due to the saline ingredients of the serum, as on depriving the serum of its salts by dialysis it was then found to exercise the same solvent action on the biurate as simple water. Sir William Roberts found that the sodium salts especially diminish the solvent power of a medium on sodium biurate, and that this diminished power is mainly, if not entirely, due to the sodium, and is apparently not much, if at all, influenced by the acids combined with it, since solutions of sodium bicarbonate, chloride, sulphate, phosphate, and salicylate, prepared so that the percentage of sodium in them was the same, exhibited the same solvent action. His experiments also show that if a medium be rich in urates, but poor in sodium salts, its tendency to precipitation is feeble, and *vice versâ*. Since structures belonging to the connective tissue class are rich in sodium salts and are also liable to uratic deposits, while muscle, brain, liver, and spleen are poor in sodium salts and not liable to uratic deposits, he considers that the proportion of sodium salts in a tissue is an important factor in determining the deposition of urates in that tissue. Another factor, according to this authority, in facilitating the precipitation of urates is to be found in the synovial fluid. Sir William Roberts's view is that the uratic precipitation actually takes place from the synovial fluid, and does not originate in the cartilaginous substance. This view is based in part on the microscopic appearance of vertical sections of gouty cartilage, in which the deposit is seen to be greatest on the synovial surface of the cartilage and to become gradually sparser and sparser towards the deeper layers, and in part on the fact that synovial fluid has been repeatedly found heavily laden with crystals of sodium biurate. He considers (as opposed to Ebstein's view) that the process of deposition in the cartilage is a purely passive and physical one, and that the synovial fluid, charged with its dissolved urate, penetrates by liquid diffusion into the superficial layers of the cartilage, and that when the critical moment arrives precipitation takes place simultaneously in the synovia and in the cartilage. According to this view the after consequences are entirely secondary, and are due to inflammation set up by the presence of the foreign body in the tissue.

As regards the varying liability of different joints to gouty attack, Sir William Roberts considers that it is, at all events in part, dependent on a greater concentration of the synovia of some joints and on a variable proportion of sodium salts and possibly of sodium biurate. The experiments made by Frerichs[2] on the comparative composition of the synovia of animals leading idle or active existences somewhat support this view. Frerichs found that the synovia of stall-fed horses and oxen leading an idle existence was more watery and contained a larger proportion of sodium salts than the synovia of similar animals doing work or roaming in the meadows. Moreover, the joints of the idle animals contained twice as much synovia as the joints of similar animals taking active exercise.

Deposition encouraged by sluggish movement of medium.—It is highly probable that the very sluggish movement of fluids in the cartilaginous and fibrous tissues favours the deposition of urates from the medium in which they are dissolved. As illustrating the fact that whatever interferes with the movement of the animal fluids favours the production of gouty symptoms and of an attack of gout itself, an interesting case has been recorded by Charcot,[3] who observed, in a hemiplegic woman aged forty years, that most of the articular cartilages on the right (paralysed), side were infiltrated with urates, whereas those of the non-paralysed side showed no such deposits. Sir William Roberts considers that the chief reason why in the post-mortem room the cartilages figure more prominently than the fibrous structures as the seat of deposition of sodium biurate is to be found in the fact that in the fibrous tissues there is a comparatively free lymph flow, which exercises a more effective solvent action on uratic deposits than can be effected by the sluggish lymph flow in the cartilages. With regard to the reason or reasons that gouty precipitation takes place preferentially in synovia rather than in the serum of blood and lymph, Sir William Roberts considers that the motionless condition of synovia as compared with the state of rapid movement of blood and lymph would give to synovia a priority in uratic precipitation. In addition, it is possible that, as Sir Alfred Garrod suggests, there is some special attraction in the joints for uric acid.

Deposition encouraged by nervous influences.—It is possible, given the condition in which there is a fair amount of sodium quadriurate or biurate circulating in the blood, the amount not being quite up to saturation point, that nervous influences may accelerate deposition of sodium biurate. It is well known that whatever produces depression of the nervous system, such as excessive exercise carried to the point of fatigue, rage, fright, worry, excitement, or venereal excess, may cause an attack of gout in a gouty subject. It appears to me that a possible explanation of this result is that nervous influence affects the kidneys and depresses their excretory power for uric acid, which is consequently absorbed into the general circulation and rapidly raises the quantity of urate in the blood to the point of over-saturation. Probably the well-known effect of an exposure to cold inducing a paroxysm of acute gout is due to a similar cause.

Deposition encouraged by abnormal constituents of the blood.—As previously stated, in cases of chronic lead poisoning there is a deficient excretion of uric acid in the urine and an accumulation of it in the blood. As to the actual way in which the lead favours or hastens the deposition of sodium biurate and so produces gout there are different opinions. Sir William Roberts[4] considers that it is difficult to believe that lead poisoning produces the same constitutional diathesis as that which exists in true gout, and prefers to think that, while gout and plumbism differ in all other respects, they have one tendency or vice in common—namely, the tendency to uratosis—that is, to the deposition of sodium biurate. He considers it is more accurate, instead of speaking of *ordinary gout* and *saturnine gout*, to speak of *gouty uratosis* and *saturnine uratosis*. It appears to me that gout and plumbism have more in common than this tendency to uratosis in that they both have the same tendency to cause the presence of an excess of urates in the blood. The association of lead poisoning with gout has been repeatedly observed, but Oliver[5] states that in the North of England this intimate relationship between gout and lead poisoning is not seen. He is not satisfied that the reason why gout is so little known in the North as a symptom of lead poisoning, while it is so common in the South, is entirely due to the difference in the drinking habits of the people—whisky being the general alcoholic drink in the North and malt liquor in the South. At the same time he confesses his inability to offer any further explanation.

I am of opinion that the influence of lead in producing gout depends solely on the extent to which the kidney parenchyma is damaged. With much damage done to the kidney cells, whose function it is to excrete uric acid, absorption of quadriurate into the blood occurs; the subsequent development of an attack of gout entirely

[1] Lectures I. and II. were published in THE LANCET of March 27th and April 3rd, 1897, respectively.

depends on the amount of absorbed quadriurate, which in its turn depends on the amount of kidney mischief.

Deposition encouraged by injury to joints or by interference with their nutrition.—A slight injury to a joint, which in a healthy person would speedily pass off, in a gouty person renders the part susceptible to the deposition of sodium biurate if sodium quadriurate be circulating in the blood. This susceptibility is probably in some way connected with an impairment of the nutrition of the affected tissues. Fagge, indeed, regarded a paroxysmal attack of gout in the light of an accident occurring in the course of an essentially chronic change in the joint affected.

As regards the relation between gout and rheumatism, Sir Alfred Garrod has remarked that if gout supervenes in individuals who have suffered from rheumatism it is generally the articulations which had been affected before that are attacked first; so that joints which have been the seat of acute rheumatism are especially predisposed in gouty subjects to become the seat of uratic deposits. Dr. Latham[6] thinks it is probable that the uric acid circulating in the blood might exert a toxic effect on certain portions of the spinal cord which control the nutrition of the joints, and so cause nutritive changes or inflammation in the joints connected with that portion of the cord; as a result of the inflammation or nutritive changes in the joints sodium biurate is deposited in them or in the tissues around the affected joints. Ebstein[7] considers that deposition of sodium biurate is dependent on, and is produced by, previous necrosis of the affected tissues, and that the uratic deposit never occurs in a normal tissue. His view is that the neutral sodium urate circulating in the blood acts as an irritant and produces necrosis of the cartilages or other tissues, in which the sodium is subsequently deposited; as a result of this necrosis he considers that an acid is developed which converts the neutral urate into acid urate, which compound is then deposited in the necrosed areas. I have already fully stated the objections to this theory. Klemperer[8] does not consider that uric acid is responsible for the necrotic changes in tissues, nor that the phenomena of gout can be due to mere crystallisation of sodium biurate from the blood, because in leucocythæmia, where an excess of urate is present in the blood, neither local necrosis nor uratic deposits occur. He believes that some unknown substances in gout lead to inflammatory and necrotic processes in various tissues; these necrotic areas then attract the uric acid from the blood, the chemical affinity of the necrotic parts for uric acid being so great that the blood cannot re-dissolve it. Von Noorden thinks the unknown substance which starts the inflammatory and necrotic processes, is a ferment, and that the uric acid crystallises out in the necrotic tissues.

Deposition encouraged by diminished alkalinity of the blood.—Various writers have put forward the opinion that uratic deposition is dependent upon a diminution of the alkalinity of the blood. Mordhorst[9] considers that the tissues affected by gout are less alkaline than the blood, and that if the alkalinity of the latter becomes lowered then deposition may take place. Dr. Haig considers that diminished alkalinity of the blood causes deposition of uric acid in the liver, spleen, fibrous tissue, and joints, and that increased alkalinity of the blood causes its re-solution. The view that diminished alkalinity of the blood causes uratic deposition and that increased alkalinity of the blood causes re-solution of the uratic deposits is in my opinion erroneous and untenable for the two following reasons: (1) The view is apparently based on the supposition that the deposit is uric acid, whereas it is sodium biurate, the solubility of which, as Sir William Roberts has shown, is not increased by increased alkalinity of the blood; and (2) from a series of experiments that I have conducted, and which will be subsequently described, it appears that a diminution of the alkalinity of a medium does not affect the deposition of sodium biurate from that medium.

Reasons for the special selection of the great toe and ear as seats of gouty deposits.—There are several reasons to account for the special causation of uratic deposits in the great toe: (1) there is the liability of the metatarso-phalangeal joint to injury from having to support the weight of the body and from being subjected to sudden shock; (2) the remoteness of the joint from the heart and the force of the circulation being consequently at its minimum at that part; and (3) the poor vascularity of the tissues of the joint. The liability of the joint to injury is shown by Sir Alfred Garrod's examinations of the great toe joints of 20 subjects known not to have had gout. In 14 he found ulceration of the cartilages of one or both joints. Of these 20 subjects, 3 were under thirty years of age and showed no ulceration of the cartilages; the remaining 17 were over thirty years of age, and of these 14, or 82 per cent., showed ulceration of the cartilages. All the subjects over fifty years of age showed ulceration. In the helix of the ear the sluggish circulation and the coldness of the organ are quite sufficient to account for the frequency with which uratic deposits are formed in that part.

Cause of the inflammation which accompanies the gouty paroxysm.—The gouty paroxysm is due to precipitation of sodium biurate, which always takes place in crystalline form, the crystals being distributed through the implicated tissue in the form of delicate needles, aggregated into tufts, bundles, and stars. When deposition occurs in cartilage the crystalline deposit acts as an irritant and causes inflammation leading to proliferation and necrosis of cartilage cells, which may be followed by erosion of cartilage and of uratic deposits and consequent displacement of the latter into the cavity of the joint. Along the borders of the cartilage, where the deposits are comparatively small and the tissues are relatively rich in capillary vessels, the inflammatory processes may produce a more luxuriant growth of the cartilage cells, resulting in the formation of ecchondroses at the margins of the articulation. Although I consider that the inflammatory part of the gouty attack is secondary to the deposition of sodium biurate crystals, yet it must be granted that such deposition should occur fairly copiously and suddenly in order to start the inflammatory process. Undoubtedly urates may deposit slowly and quietly in joints without the development of any acute attack, or for some time antecedent to the development of an acute attack. The observations of Moxon and Fagge support the conclusion that the discovery after death of uratic deposits in a joint is not always to be regarded as a certain proof that the joint has passed through an inflammatory gouty attack. Sir Alfred Garrod's views, which are shared by Sir William Roberts and supported by abundant evidence, are in favour of the deduction that the deposition of crystalline biurates is not merely an accompaniment, but is the direct cause of the joint troubles of gout. It is therefore of practical importance to know what are the various factors or conditions which may influence the conversion of sodium quadriurate into biurate, which may alter the solubility of sodium biurate in the blood, lymph, and synovia, and which may affect the precipitation of the sodium biurate.

CERTAIN CONDITIONS AND FACTORS AFFECTING THE SOLUBILITY AND THE PRECIPITATION OF SODIUM QUADRIURATE AND SODIUM BIURATE.

Diminution of the alkalinity of the blood.—It is well known that an attack of gout may be accelerated by ingestion of food or beverages harmful either as regards their quality or quantity. Such substances may exert a direct or indirect chemical action which facilitates the precipitation of sodium biurate—this is the chemical view; or they may possibly exert a physical action only in hastening such precipitation—this is the mechanical view. A view to which I have previously referred, which is commonly held as to the influence of diet and certain beverages in accelerating an attack of gout, is that such substances reduce the alkalinity of the blood and so hasten the precipitation of sodium biurate. As I believe this view to be erroneous I will ask your attention to a consideration of my reasons for holding this opinion. It is remarkable what a number of writers incline to the view that diminution of the alkalinity of the blood causes the deposition from it of sodium biurate, and that a subsequent rise in alkalinity causes solution of the previously formed deposits. It is assumed that a nitrogenous animal diet diminishes the alkalinity of the blood and so causes deposition of sodium biurate. It is also assumed that a similar result is caused by the acids contained in wines and beers, and that the pains in the joints that frequently occur in gouty subjects soon after taking certain wines or beers are due to deposition of biurate following on the reduction of the alkalinity of the blood by the acid so introduced. Now, in the first place, is there any substantial proof that the alkalinity

Hosted by Google

of the blood is much reduced in connexion with gout? Careful experiments by Klemperer[10] that have recently been conducted show that the alkalinity of the blood of gout is but very little, if at all, diminished, and that corresponding variations in the alkalinity may frequently be met with in healthy individuals. There is certainly no good ground for the belief that an "acid dyscrasia" underlies the gouty condition. Recent researches show that a diminution of the alkalinity of the blood is a common pathological condition in diseases that are in no way associated with uratic precipitation, such as acute rheumatism, leukæmia, diabetes, carcinoma, and pyrexia. In the second place I have been unable to meet with any experimental proof that a diminution in the alkalinity of blood containing uric acid in solution either facilitates the deposition of sodium biurate from it or diminishes its solvent power for sodium biurate or for uric acid. I therefore considered it advisable to experimentally investigate these different points, and for that purpose the following series of experiments was undertaken.

I. *Experiments showing to what extent the rate of formation and precipitation of sodium biurate is affected by diminishing, by the addition of acids, the alkalinity of blood serum charged with uric acid.*—Seven bottles, each containing 40 c.c. of blood serum, were raised to 100° F. and then charged with uric acid to the extent of 1 in 1000. As soon as the uric acid was dissolved varying quantities of hydrochloric acid were added to the contents of three of the bottles, and of tartaric acid to another three, so as to partially reduce the alkalinity of the serum; the contents of the seventh bottle were left unaltered. The bottles were kept in a warm chamber at 100° F., and the commencement of the precipitation of sodium biurate crystals was then looked for by examining some of the contents of the bottles under the microscope every few minutes so as to note the time when the formation of biurate crystals commenced. The quantities of hydrochloric acid added to the contents of three of the bottles were such as to neutralise respectively three-fourths, one-half, and one-fourth of the alkalinity of the serum remaining after solution of the uric acid. To the other three bottles corresponding quantities of tartaric acid were added to produce similar results. The following tables (Table V. and Table VI.) show the results of these experiments.

TABLE V.—*The Results of Experiments made with Blood Serum charged with Uric Acid to show the effect which the Diminution of the Alkalinity of the Serum by the addition of Hydrochloric Acid has on the Precipitation of Sodium Biurate.*

Solution.	Commencement of precipitation.
Blood serum containing 1 in 1000 uric acid	Crystals of sodium biurate first appeared in from 6 to 7 hours.
The same one-fourth neutralised by hydrochloric acid	
The same one half neutralised by hydrochloric acid	
The same three-fourths neutralised by hydrochloric acid	Some crystals of uric acid appeared in 5 minutes. Crystals of sodium biurate first appeared in 12 hours.

It will be seen from the results of these experiments that the effect of diminishing the alkalinity of blood serum as far as one half has no influence whatever in hastening the conversion of the sodium quadriurate into biurate, or, in other words, does not influence the deposition of sodium biurate from the serum. When the alkalinity is reduced by three-fourths by the addition of hydrochloric acid some crystals of uric acid were almost immediately precipitated, but when this precipitation of uric acid had ceased then the deposition of sodium biurate did not begin till twelve hours had elapsed. The reason that the deposition of sodium biurate was delayed a longer time than in the cases of the serum the alkalinity of which was reduced respectively by one fourth and one-half was that the removal of some of the uric acid rendered the solution of sodium quadriurate weaker, and, as has been pointed out by Sir William Roberts, the amount of uric acid in solution exercises a very important influence on the rate of maturation of the quadriurate and on the advent of precipitation of the biurate. This early shower of uric acid crystals that occurred when sufficient hydrochloric acid was added to the blood serum to neutralise three-fourths of its alkalinity has no bearing whatever on the chemistry of the gouty attack, since the gouty deposit always consists of sodium biurate and never of uric acid. The following table shows the results of the experiments with tartaric acid and blood serum.

TABLE VI.—*The Results of Experiments made with Blood Serum charged with Uric Acid to show the Effect which the Diminution of the Alkalinity of the Serum by the Addition of Tartaric Acid has on the Precipitation of Sodium Biurate.*

Solution.	Commencement of precipitation.
Blood serum containing 1 in 1000 uric acid	Crystals of sodium biurate first appeared in from 6 to 7 hours.
The same, one-fourth neutralised by tartaric acid	
The same, one-half neutralised by tartaric acid	
The same, three-fourths neutralised by tartaric acid ...	

From these experiments it is evident that even the reduction of the alkalinity of blood serum by three-fourths has no influence in hastening the precipitation of sodium biurate from blood serum impregnated with uric acid. The view, therefore, that a diminution of the alkalinity of the blood promotes an attack of gout by favouring the deposition of sodium biurate is, in my opinion, untenable. In order to give an idea of the amount of acid that would be required to reduce the alkalinity of the blood of an adult human being by three-fourths I made the following estimation and calculation. I found that the acidity of some 1847 port, reckoned as tartaric acid, was equal to six grains of acid to the wineglassful. In order to neutralise three-fourths of the alkalinity of the blood serum of a man of average weight it would be necessary that all the acid contained in two bottles of such port should be introduced at one moment into the circulation. It appears to be very doubtful indeed whether there really is any appreciable diminution of the alkalinity of the blood in gout. Klemperer[11] examined the alkalinity of the blood in three gouty cases and found that it was only slightly diminished. He found a much more conspicuous diminution of alkalinity in other morbid conditions which are not associated with the deposition of sodium biurate.

II. *Experiments to show the solvency of uric acid in blood serum the alkalinity of which has been reduced by the addition of an acid.*—The effect of hydrochloric and tartaric acids respectively was investigated. As will be seen from the results, there is a remarkable difference in the solvent power of partially neutralised blood serum for uric acid accordingly as its alkalinity is reduced by the addition of hydrochloric or tartaric acids. The experiments were carried out in the following manner. Four bottles containing 25 c.c. each of blood serum were taken; three of them were treated respectively with different quantities of hydrochloric acid so as to reduce the alkalinity of the serum in one case by one-fourth, in the second case by one-half, and in the third case by three-fourths; the contents of the remaining bottle were left untouched. The bottles were placed in the warm chamber till their contents were at 100° F., and then an excess (from 60 to 70 milligrammes) of uric acid was added to each. They were kept in the warm chamber for two hours, during which time they were frequently agitated; the contents of the bottles were then filtered from undissolved uric acid, and the dissolved uric acid in each filtrate was estimated. The following table shows the results.

TABLE VII.—*Showing the Solubility of Uric Acid at 100° F. in Unaltered Blood Serum, and in Blood Serum the Alkalinity of which is Proportionately Reduced by the Addition of Hydrochloric Acid.*

Solvent.	Uric acid dissolved.
Unaltered serum	2·03 per 1000
Serum one-fourth neutralised by hydrochloric acid	1·48 ,,
Serum one-half neutralised by hydrochloric acid	1 00 ,,
Serum three-fourths neutralised by hydrochloric acid	0 45 ,,

Similar experiments were carried out using tartaric acid in the place of hydrochloric acid. The following table shows the results.

TABLE VIII.—*Showing the Solubility of Uric Acid at 100° F. in Unaltered Blood Serum, and in Blood Serum the Alkalinity of which is Proportionately Reduced by the addition of Tartaric Acid.*

Solvent.	Uric acid dissolved.
Unaltered serum	2·03 per 1000
Serum one-fourth neutralised by tartaric acid	2·01 ,,
Serum one-half neutralised by tartaric acid	2·01 ,,
Serum three-fourths neutralised by tartaric acid	2·02 ,,

It is seen from the results of these experiments that if the alkalinity of blood serum is reduced by the addition of hydrochloric acid the solvency of the serum for uric acid is correspondingly altered. This is what one would expect, since the conversion of some of the sodium bicarbonate of the serum into sodium chloride renders that portion of the sodium unattainable by the uric acid and prevents the solution of a corresponding amount of the latter as sodium quadriurate. Such a result, however, does not follow the reduction of the alkalinity of the serum by the addition of an organic acid such as tartaric acid. It will be seen that serum, the alkalinity of which is reduced respectively by one-fourth, one-half, and three-fourths, practically does not vary at all as regards its solvency for uric acid. The explanation, no doubt, is that the uric acid is able to displace the tartaric acid from its combination with sodium and utilise the sodium of the tartrate as readily as the sodium of the bicarbonate to form the soluble sodium quadriurate. Since the acidity of wines is due to organic acids (mainly tartaric, malic, and succinic acids) it would seem very doubtful, judging from the results of these experiments, whether, even if any alteration in the alkalinity of the blood were produced by the drinking of acid wines, the solubility of uric acid in such blood could be affected in the slightest degree.

III. *Experiments to show the solvency of sodium biurate in blood serum the alkalinity of which has been reduced by the addition of an acid.*—The effect of hydrochloric and tartaric acids respectively was investigated. The experiments were carried out in a similar manner to those just described, except that an excess of sodium biurate was substituted for the uric acid and the digestion with the sodium biurate was carried on at 100° F. for five hours. The following tables show the results.

TABLE IX.—*Showing the Solubility of Sodium Biurate at 100° F. in Unaltered Blood Serum, and in Blood Serum the Alkalinity of which is Proportionately Reduced by the Addition of Hydrochloric Acid.*

Solvent.	Sodium biurate dissolved.
Unaltered serum	0·05 per 1000
Serum one-fourth neutralised by hydrochloric acid	0·05 ,,
Serum one-half neutralised by hydrochloric acid	0·07 ,,
Serum three-fourths neutralised by hydrochloric acid	0·10 ,,

These results show that sodium biurate is slightly more soluble in serum which has been partially neutralised by the addition of hydrochloric acid than it is in unaltered serum.

TABLE X.—*Showing the Solubility of Sodium Biurate at 100° F. in Unaltered Blood Serum, and in Blood Serum the Alkalinity of which is Proportionately Reduced by the Addition of Tartaric Acid.*

Solvent.	Sodium biurate dissolved.
Unaltered serum	0·05 per 1000
Serum one-fourth neutralised by tartaric acid	0·08 ,,
Serum one-half neutralised by tartaric acid	0·08 ,,
Serum three-fourths neutralised by tartaric acid	0·12 ,,

These results also show that sodium biurate is more soluble in serum the alkalinity of which has been reduced by the addition of tartaric acid than it is in unaltered serum. I think that the view that uric acid is deposited in the liver, spleen, joints, and fibrous tissues owing to diminished alkalinity of the blood should be abandoned. It is based on an error—viz., that the deposit is uric acid, whereas it is sodium biurate. The results of the experiments that I have just described indicate that diminution of the alkalinity of the medium does not promote the deposition of sodium biurate. The other view, that increased alkalinity of the blood dissolves and sweeps out the accumulations of uric acid from the various organs and tissues, should also, in my opinion, be abandoned. It is based on the same error—viz., that the deposit is uric acid, whereas it is sodium biurater. That this body is not more soluble in highly alkaline fluids has been proved by the experiments of Sir William Roberts,[12] and is confirmed by the experiments that I have just described.

Certain drugs reputed to facilitate the deposition of uric acid.—Another erroneous idea, in my opinion, is that uric acid may be precipitated from the blood in the form of insoluble urates by certain metallic salts; these insoluble urates are supposed to be deposited in various tissues or organs, and yet in some mysterious manner to be subsequently re-dissolved when the alkalinity of the blood rises. There is absolutely no experimental proof to support such statements. Dr. Haig is, I believe, the chief apostle of these doctrines. As an instance of their erroneous nature I will briefly refer to Dr. Haig's[13] statement that "calomel clears uric acid out of the blood and retains it in the body by forming an insoluble urate of mercury." This statement is based on the fact that solutions of urates give with *soluble* salts of mercury a precipitate of urate of mercury. But how can an insoluble compound like calomel act in such a manner? It might be assumed that the calomel first forms in the system a soluble salt of mercury. If such were the case, then every time we give a full dose of calomel we should kill the patient by acute mercurial poisoning. Moreover the error of Dr. Haig's deduction is illustrated by observing the amount of uric acid supposed to be converted into urate of mercury. He mentions only one experiment in which half a grain of calomel is supposed to precipitate and retain in the system as urate of mercury 1·4 grains of uric acid. Now, even allowing that all the mercury in the half-grain of calomel is capable of forming urate of mercury, then it could only combine with one-fourth of the 1·4 grains of uric acid supposed to be precipitated by its means. Yet from this one assumed retention of uric acid by calomel Dr. Haig[14] remarks: "Mercury diminishes the excretion of uric acid in the urine, clears it out of the blood and retains it in the body, because it forms with it an insoluble compound, and it is therefore a single instance of my law of solubilities."

Influence of certain articles of diet on the precipitation of sodium biurate.—It is well known that the excessive consumption of rich nitrogenous food, combined with excesses in wine and malt liquors, both induce and excite gout. The comparative immunity of females and young people from gout is mainly explained by the absence of such determining causes of the gouty attack, combined with, in the case of young people, the absence of predisposing causes, and also the fact that the secreting functions are in full activity. The subjects of gout are generally persons who live well and consume a large amount of animal food. Dr. Budd, speaking from a long and extensive professional connexion with a large rural district, states that he never knew an instance of gout occurring among agricultural labourers. The generally accepted view that a highly nitrogenised animal diet necessarily produces an excessive amount of uric acid is disproved by the experiments, previously referred to, of Bleibtreu and of Hirschfeld. These experiments show that there is an increased elimination of urea to compensate for an excessive intake of nitrogenous food, and that the amount of uric acid remains practically undiminished. Judging by the results of the experiments which I have undertaken and previously described, it is highly improbable that any diminution in the alkalinity of the blood which might be produced by the consumption of an excessive amount of animal food could in any way affect its solvent powers for uric acid or accelerate the precipitation of sodium

biurate. My own view is that, as regards the production of uric acid from proteid matter, it is of little importance whether the proteid is of animal or vegetable origin; the same harm may result from an excessive consumption of either form of proteid. But although animal and vegetable proteids may react alike with regard to the production of uric acid, it is quite possible that the different saline constituents of animal and vegetable foods might very materially affect the solubility of sodium biurate and therefore influence its precipitation. As I have been unable to find any record of experimental work bearing on this matter, I thought it advisable to ascertain if the saline substances contained in different articles of diet appreciably affected the solvency of sodium biurate at the temperature of the human body, as obviously the subject might have both a pathological and therapeutical bearing. The following experiments were therefore carried out.

Experiments showing the influence of the mineral constituents of meat, milk, and vegetables respectively on the solubility of sodium biurate at 100° F.—A series of experiments were undertaken, operating upon the ash respectively of lean beef, milk, and mixed vegetables (potatoes, spinach, and French beans). The experiments were carried out in the following manner, which is similar to the method adopted by Sir William Roberts in determining the influence of various therapeutical salts on the solubility of sodium biurate. The contents of a number of bottles each containing 100 c.c. of distilled water were mixed with known quantities of the different ashes and placed in the warm chamber until they were at a temperature of 100° F., when an excess of sodium biurate was added to each. The bottles were kept at 100° F. for five hours, during which period they were frequently agitated. At the end of that time the contents of the bottles were filtered and re-filtered through double filters until perfectly clear filtrates were obtained. The amount of uric acid in each of the filtrates was then estimated by adding an excess of strong sulphuric acid and titrating with the standard potassium permanganate solution: the quantity of uric acid found was subsequently calculated into terms of sodium biurate. The results thus obtained are shown in the following tables. The solubility of sodium biurate in distilled water is placed at the head of each table for comparison.

TABLE XI.—*Showing the Influence of the Mineral Constituents of Meat (lean beef) on the Solubility of Sodium Biurate at 100° F.*

Solvent.	Sodium biurate dissolved.
Water	1·10 per 1000.
Water containing:—	
1·0 per cent. of meat ash	0·93 ,,
0·5 ,, ,, ...	0·76 ,,
0·2 ,, ,, ...	0·56 ,,
0·1 ,, ,, ...	0·32 ,,
0·05 ,, ,, ...	0·15 ,,
0·02 ,, ,, ...	0·11 ,,
0·01 ,, ,, ...	0·85 ,,

From the above table it is seen that the mineral constituents of meat in all proportions between 1·0 and 0·01 per cent. diminish the solvency of sodium biurate. The effect is most marked when the proportions are between 0·1 and 0·02 per cent., which are proportions that may certainly be present in the blood after eating a few ounces of meat. It is therefore quite possible that the well-known influence of excessive meat eating on the hastening or maturing of an attack of gout may, in part at least, be due to the action of the mineral constituents of the meat.

From Table XII. it is seen that the mineral constituents of milk in all proportions diminish the solvency of sodium biurate. The effect is most marked when 0·1 per cent. of milk ash is present. It is extremely unlikely that such a proportion could be present in the blood unless a person were exclusively fed for some time on milk. To introduce 0·1 per cent. of the mineral constituents of milk into the blood would require that all the mineral constituents of about twenty-two ounces of milk should be introduced at one moment into the blood of an adult of average weight. These experiments therefore seem to indicate that the mineral constituents of milk can exercise no appreciable influence in hastening or maturing an attack of gout.

TABLE XII.—*Showing the Influence of the Mineral Constituents of Milk on the Solubility of Sodium Biurate at 100° F.*

Solvent.	Sodium biurate dissolved.
Water	1·10 per 1000
Water containing:—	
1·0 per cent. of milk ash	0·62 ,,
0·5 ,, ,, ...	0·58 ,,
0·2 ,, ,, ...	0·49 ,,
0·1 ,, ,, ...	0·44 ,,
0·05 ,, ,, ...	0·72 ,,
0·02 ,, ,, ...	0·90 ,,
0·01 ,, ,, ...	0·94 ,,

From Table XIII. it is seen that the mineral constituents of vegetables in quantities of 0·1 per cent. and above very appreciably increase the solvency of sodium biurate. In quantities below 0·1 per cent the solutions exercise the same solvent power on the biurate as distilled water.

TABLE XIII.—*Showing the Influence of the Mineral Constituents of Vegetables (potatoes, spinach, and beans) on the Solubility of Sodium Biurate at 100° F.*

Solvent.	Sodium biurate dissolved.
Water	1·10 per 1000.
Water containing:—	
1·0 per cent. of vegetable ash	2·15 ,,
0·5 ,, ,, ...	1·70 ,,
0·2 ,, ,, ...	1·35 ,,
0·1 ,, ,, ...	1·15 ,,
0·05 ,, ,, ...	1·10 ,,
0·02 ,, ,, ...	1·10 ,,
0·01 ,, ,, ...	1·10 ,,

These experiments indicate that the mineral constituents of vegetables, if taken in sufficient quantities, would delay the advent of an attack of gout by increasing the solvency of sodium biurate.

I next endeavoured to ascertain whether the mineral constituents of milk, meat, and vegetables possessed any inhibitory powers over the decomposition of sodium quadriurate; and, if so, what were their comparative powers. It has been demonstrated by Dr. Bence Jones and by Sir William Roberts that the quadriurates, which consist of a molecular combination of a biurate with uric acid, are resolved by the action of water into moieties—the biurate moiety, which is dissolved by the water, and the uric acid moiety which is precipitated in the form of ovoid crystals. My object was to ascertain whether this change was delayed by the presence, in the water of small quantities of the mineral constituents of milk, meat, and vegetables respectively; and, if so, what the relative inhibitory powers of these constituents were. In connection with this investigation some very remarkable results were obtained. The method I employed was that originally used by Sir William Roberts. Some pure sodium quadriurate was prepared by the method described by him. A very small quantity was placed on a glass slide, and stirred up with a drop of water. A cover slip was applied, and the result watched under the microscope. The time was noted at which crystals of uric acid began to make their appearance. Fresh quantities of quadriurate were then treated in a similar manner with 0·1 per cent. solutions of the mineral constituents of milk, meat, and vegetable ash respectively, and the different times at which crystals of uric acid commenced to form were noted. These were compared with the time required by distilled water to start the decomposition, which was taken as the standard of comparison. It was found that when the quadriurate was treated with distilled water crystals of uric acid commenced to form at the end of half a minute, when treated with a 0·1 per cent. solution of milk ash in distilled water at the end of half a minute, with a 0·1 per cent. solution of meat (lean beef) ash at the end of one minute, and with a 0·1 per cent. solution of mixed vegetable (potato, spinach, and beans)

Hosted by Google

ash at the end of two hours. Taking, for purposes of comparison, the time occupied by distilled water to start the decomposition as unity, the comparative influences exerted on the decomposition of the quadriurate by 0·1 per cent. solutions of the mineral constituents of milk, meat, and vegetables respectively are shown in the following table.

TABLE XIV.—*Showing the Comparative Inhibitory Powers on the Decomposition of Sodium Quadriurate possessed by Distilled Water and by 0·1 per cent. Solutions of the Mineral Constituents of Milk, Meat, and Vegetables respectively.*

Medium.	Comparative inhibitory power.
Distilled water	1
0·1 per cent. solution of milk ash	1
0·1 per cent. solution of meat ash	2
0·1 per cent. solution of vegetable ash	240

These results show that a 0·1 per cent. solution of milk ash acts precisely as does distilled water on the decomposition of the quadriurate; that a 0·1 per cent. solution of meat ash delays the decomposition of the quadriurate twice as long as distilled water, but still only for a very brief period; and that a 0·1 per cent. solution of vegetable ash delays the decomposition of the quadriurate 240 times as long as distilled water, and 120 times as long as does the meat ash solution. It must be borne in mind that the action of distilled water in causing decomposition of the quadriurate is very rapid as compared with blood serum, as the latter takes some hours to effect decomposition. It is highly probable that the addition of a small proportion of the mineral constituents of vegetables to blood serum would delay decomposition of the quadriurate for a very considerable period of time. I propose to further investigate this matter and to endeavour to ascertain to which of the saline constituents of vegetables this remarkable inhibitory power belongs The investigation appears to be a promising one, but time has not allowed me to prosecute it further at present. The net results of these experiments and of those previously described indicate that the mineral constituents of meat only delay for a brief period the decomposition of the quadriurate, and when it is once decomposed they hasten the precipitation of the biurate. On the other hand, the results indicate that the mineral constituents of vegetables delay for a remarkably long period the decomposition of the quadriurate, and then subsequently retard the precipitation of the biurate by increasing its solvency. I do not wish to attribute the different effects of animal and vegetable diets on gouty subjects to the saline constituents alone, but it is, I think, to the different mineral constituents of animal and vegetable foods and to the different effects they have on the quadriurates and biurates that we must look for at least a partial explanation—perhaps a main one—of the known facts that an excessive diet of the one tends to produce gout and of the other tends to retard it.

Influence of alcoholic drinks on the gouty process.—It is well known that certain alcoholic drinks injuriously affect the gouty process, whilst others exert a less injurious influence. Alcoholic drinks which have been obtained by fermentation, but which have not been submitted to distillation, such as wines and beers, appear to exercise a more harmful influence than if the same amount of alcohol be consumed in the form of one of the distilled spirits, such as whisky, brandy, &c. Sir Alfred Garrod considers that the reason for the prevalence of gout in the South of England and its rarity in Scotland is chiefly due to the different beverages drunk in the two countries. Distilled spirits contain little or no acid, whilst wines and beers are distinctly acid, and to the acids contained in these drinks many physicians have attributed, and still do attribute, their gout-inducing properties. The acids present are tartaric, succinic, malic, acetic, formic, propionic, butyric, and œnanthic. The acidity of wines is mainly due to tartaric, malic, and succinic acids. The amount of free acid in sound wine, reckoned as tartaric acid, varies between 0·3 and 0·7 per cent. I found the acidity of some 1847 port, reckoned as tartaric acid, to be 0·6 per cent. Cider owes its acidity mainly to malic acid. Its total acidity is usually 0·1 per cent. If we arrange the various wines in (*a*) their order of acidity, and (*b*) the order of their gout-inducing power, we find that the most acid wines are not those which most predispose to gout. The arrangement of wines and beers in the order of acidity, beginning with the most acid, is that given by Dr. Bence Jones, while the arrangement in the order of their gout-inducing power is that given by Sir Alfred Garrod.

TABLE XV.—*Wines and Beers arranged in order of Acidity and Gout-inducing Power.*

Acidity (beginning with the most acid).	Gout-inducing power (beginning with the most powerful).
Moselle.	Port.
Rhine wines.	Sherry.
Burgundy.	Other stronger wines.
Madeira.	Champagne.
Claret.	Stout and porter.
Champagne.	Strong ales.
Port.	Claret.
Sherry.	Hock.
Malt liquors.	Moselle.
	Weaker kinds of ales.

Claret, hock, moselle, and the weaker kinds of ales have comparatively little gout-inducing power.

Sir Alfred Garrod considers that acidity of alcoholic liquors cannot have much influence in determining an attack of gout, as port, sherry, and malt liquors, which are the most powerful predisposing agents, are amongst the least acid; whilst the more acid wines, such as clarets, are comparatively harmless in this respect. This opinion is entirely borne out by the experiments I have described in this lecture, which show that a dimunition of the alkalinity of blood serum does not hasten the conversion of sodium quadriurate into biurate, does not diminish the solubility of sodium biurate, and therefore cannot promote deposition of sodium biurate, and so be a determining cause of an attack of gout. The question is, To what constituent or constituents of wines and beers are their gout-inducing properties due? They are not due to the alcohol alone; for in countries such as Scotland, Norway, Sweden, and Poland, where distilled spirits are, or were, freely consumed, gout is almost unknown. Moreover, several experiments that I have made indicate that alcohol, in such quantities as it is ever likely to be present in the blood, has no effect either upon the conversion of sodium quadriurate into biurate or on the solubility of the latter. The gout-inducing properties are most probably not due to the acids of the wines and beers, for the reasons which I have already given. They are also most probably not due to the sugar. The late Dr. George Harley experimentally investigated the subject and stated that the popular notion as to the pernicious effects of sugar in cases of gout is open to grave criticism, seeing that not only can no reliable facts be adduced in favour of the statement, but no reliable authority for the assertion can be cited even by its believers. I have myself found experimentally that sugar has no appreciable effect either on the decomposition of sodium quadriurate or on the solubility of sodium biurate. The gout-inducing properties are certainly not directly due to the œnanthic ether and other ethereal salts of wines exerting any effect either on the rate of decomposition of the sodium quadriurate or on the solubility of the biurate. To demonstrate these points I have extracted from old port wines the ethereal salts to which the bouquet of the wines is due, and have experimented with these ethereal compounds on the quadriurates and biurates. Using quantities far in excess of those likely to be present in the blood after the moderate, or even immoderate, consumption of such wine, I find that none of these volatile constituents exercise the slightest effect either in hastening the decomposition of sodium quadriurate, or in diminishing the solubility or hastening the precipitation of sodium biurate. As to the *modus operandi* of certain wines, such as port, &c., in hastening an attack of gout, I am not at present prepared with an explanation, as I have not yet completed the experiments I am conducting with the view of endeavouring to throw some light on the subject. I, however, incline to the opinion that the influence of wines on the development of gout is in great part due to the effect they have on the metabolism of the liver, and the consequent increased amount of glycocine that passes on to the kidneys. At the same time it must be remembered that those

Hosted by Google

accustomed to drink wine are also able to indulge in other luxuries of the table which greatly favour the development of gout.

CONCLUSIONS.

The main points and conclusions arrived at in these lectures are as follows:—1. Uric acid is not normally present in the blood of man and other mammals, nor in the blood of birds. 2. Uric acid is normally produced only in the kidneys. 3. Uric acid is normally formed from urea, probably by conjugation of that substance with glycocine in the kidneys. 4. Uric acid is present in the blood in gout as the soluble sodium quadriurate. In its soluble form it is not a toxic agent. It deposits from the blood as sodium biurate, which acts passively and physically as a foreign body in the tissues or organs in which it is deposited. 5. The presence of uric acid in the blood in gout is due to its deficient excretion by the kidneys and to the subsequent absorption of the non-excreted portion into the blood from those organs. 6. Gout is probably always preceded by some affection of the kidneys, functional or organic, which interferes with the proper excretion of uric acid. The probable seat of the kidney affection giving rise to gout is in the epithelium of the convoluted tubes. 7. In certain blood diseases and disorders accompanied by leucocytosis uric acid is formed within the system from nuclein. Under such circumstances it passes at once into the blood and is rapidly eliminated by the kidneys. 8. The solubility of uric acid in the blood is not affected by a diminished alkalinity of the blood produced by the addition of organic acids. 9. The deposition of sodium biurate is not accelerated by a diminution of the alkalinity of the blood. 10. An increased alkalinity of the blood does not increase the solubility of deposits of sodium biurate. 11. The saline constituents of vegetables exercise a remarkable inhibitory power over the decomposition of sodium quadriurate. 12. The solubility of sodium biurate in the blood is increased by the presence of the saline constituents of vegetables. 13. The solubility of sodium biurate in the blood is diminished by the presence of the saline constituents of meat. 14. The gout-inducing properties of certain wines are not due to their acidity. Probably they owe their gout-inducing action to the effect they exercise on the metabolism of the liver.

NOTE ON LACTOSURIA.

BY F. W. PAVY, M.D. LOND., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

A CASE of saccharine urine in connexion with lactation that has recently fallen under my observation has prompted these few remarks upon the subject. Mention has been for a long time made of the condition, and a considerable amount of literature is to be found regarding it. It is a matter which is quite devoid of any intrinsic importance, but at the same time may in certain instances give rise for a while to a considerable amount of mental disquietude.

In the case in question the patient was first seen by the country medical attendant of the family and was brought to me by the London medical attendant. Attention was in the first instance drawn to the state of the urine by an unusually frequent desire for micturition being experienced by the patient. She had been suffering for a little time from dyspeptic troubles, and through these was weaning her child which she had been nursing for a period of five months. She reduced the times of nursing to twice daily for a few days and then ceased altogether, without having recourse to artificial means for the removal of the milk. The breasts were hard and lumpy and a little tender, but showed nothing more. It was at this period that the urine was examined and found to be of specific gravity 1040 and to give a strong reaction of sugar, the quantity indicated by the copper test being eight grains per fluid ounce (19 per 1000). Hopes were entertained when the discovery of the presence of sugar was made that it might be due to a re-absorption of milk sugar, but anxiety was created on account of the family history of diabetes in the mother. When I saw the patient, three days after the sugar had been recognised, she had been placed on a restricted diet, with the administration of codeina. A specimen of the urine passed on going to bed on the previous night was of specific gravity 1036. It gave an indication of containing 6·75 per 1000 of sugar reckoned as glucose. The urine passed on rising in the morning was of specific gravity 1034. The figures for sugar stood at 5·26 per 1000. Both specimens had thrown down a copious deposit of urates, and it had been noticed that the amount of urine passed was considerably below the normal. I suggested that the state of the urine should be watched with a trial of a gradually advancing liberty of diet if circumstances should be found to permit. I subsequently learnt that the sugar soon disappeared, and when I saw the patient two months later she appeared to be in good health, was taking ordinary food, and passing urine free from sugar. In order to subject her condition to a thorough test she was desired to partake to a fuller extent than ordinarily of starch and sugar-containing articles of food. A fortnight later the urine was again found to be free from sugar.

The high specific gravity of the urine in this case when the sugar was first recognised contributed to excite alarm. It arose, as not unfrequently happens with ladies, from undue concentration dependent upon the ingestion of an insufficient quantity of liquid to permit of the secretion presenting its ordinary state.

With the advance of knowledge that has latterly taken place we have now at our disposal the means of readily differentiating lactosuria from true glycosuria. In former times it was different, and the sugar of lactosuria was assumed to be the same as that met with in diabetes. Hofmeister[1] in 1877 conducted an inquiry into the nature of the sugar present, and found that in the saccharine urine associated with the puerperal state the sugar presented the characters of lactose instead of those of glucose; and it is now admitted that in the form of saccharine urine under consideration lactose, and not glucose, is present. It would seem that a slight amount of lactosuria is of very common occurrence, but it is only where the secretion of milk is profuse enough to lead to an undue accumulation in the gland, or where from any cause undue retention occurs, that marked lactosuria is met with. According to the observations undertaken by Ney[2] in the Midwifery Clinic at Basle, in 152 cases where attention was given to the state of the urine after childbirth a reaction with the sugar tests was obtained in 77 per cent. With a natural progress after childbirth Ney argues that the occurrence of a saccharine reaction may be taken as an indication of the possession of good nursing capacity on the part of the mother. It shows that milk is secreted in such abundance as to lead to a re-absorption of some of its sugar.

The presence of sugar other than glucose was determined in the case under consideration by means of its cupric oxide reducing power taken before and after boiling with sulphuric acid and also by treatment with phenyl-hydrazine. Boiling with sulphuric acid, associated with the application of the copper test, affords a most useful means of determining the kind of carbohydrate that has to be dealt with. I have used the procedure very largely in my physiological researches, and it has proved of the highest value. I have applied it to the urine of diabetes in a large number of instances, and only upon exceptional occasions have I found that it has done otherwise than indicate the presence of glucose. In the case before us the cupric oxide reducing power stood much below that of glucose. As a matter of fact the figures obtained were below the figures ordinarily taken to represent the cupric oxide reducing power of lactose. The osazone crystals obtained on treatment with phenyl-hydrazine did not agree with those of glucosazone, but, on the other hand, corresponded with those yielded by a low cupric oxide reducing sugar like lactose.

The elimination of lactose under the circumstances in which it is found has an interest of another nature besides that belonging to the clinical aspect of the question. It has a bearing of fundamental importance in relation to the physiology of the carbohydrates, touching as it does the consideration of their mode of application within the animal system. Under the doctrine that implies a functional transit of sugar through the circulation an insuperable difficulty is presented. All evidence goes to show that whenever sugar, no matter of what kind, reaches the general circulation it becomes revealed in the urine. For sugar to be kept out of the urine it must as a preliminary condition be kept out of the general circulation, and this is effected with the carbohydrate of alimentation by its being disposed of before the opportunity is afforded of its reaching the systemic

[1] Zeitschrift für Physiologische Chemie, Band i., p. 101.
[2] Archiv für Gynäkologie, Band xxxv., p. 239.

Hosted by Google

vessels. It has always been a puzzling matter under the old view that sugar supposed to reach the general circulation through the portal system from the alimentary canal should readily disappear, whilst after direct introduction by subcutaneous or intravenous injection it should remain susceptible of recognition and become discharged with the urine. With reference to milk sugar in relation to this point, von Noorden [3] writes: "We have here in the case of milk sugar to do with a substance which is in an eminent degree a physiological nutrient material, a substance which is taken in 'milk-cures' to the amount of from 100 to 150 grammes a day, and which can be ingested by most healthy individuals in single doses of 100 grammes and be rapidly absorbed without a trace escaping decomposition and appearing in the urine. Why, then, should a nursing woman excrete in the urine the certainly very small amount of sugar which she has elaborated in her own mammary glands and which has been thence taken up in the blood? A number of researches which I have made with a view to a solution of this problem have led me to the hypothesis that in the puerperal state the capacity of the tissues for breaking up milk sugar is diminished. We have here an instance of adaptation to an end, in that the cells of the mother refuse a material which is pre-eminently suited to the nutritive wants of the nursling."

The fact is, the milk sugar which is received into the alimentary canal does not reach the general circulation, as hitherto supposed, but becomes assimilated or disposed of instead. Experiment shows that if it did reach the general circulation the fact would be indicated by its passage into the urine. I have found that the injection of lactose only to the extent of one gramme per kilo of body weight, either subcutaneously or intravenously, gives rise to an enormous appearance of lactose in the urine. In absorption from the mammary gland the position may be looked upon as identical with that in absorption from the subcutaneous tissue, and when circumstances exist to lead to its occurrence the passage of lactose into the urine occurs. Lactose, then, cannot be conveyed as such in the blood to the mammary gland for separation by secretion any more than, as I contend, sugar can be conveyed to the tissues for destruction. In either case the urine would infallibly afford indication of the transit. Under the glucoside constitution of proteid matter set forth by me in my "Physiology of the Carbohydrates" carbohydrate matter can be transported without being in a position to run off with the urine, and with lactose taking origin as a cleavage product in the mammary gland all difficulty is overcome. It is quite obvious that if lactose reached the mammary gland, as such, for secretion it would similarly reach the kidney for elimination. By analogy the position of lactose throws light upon the broad question of the physiology of the carbohydrates in the animal system.

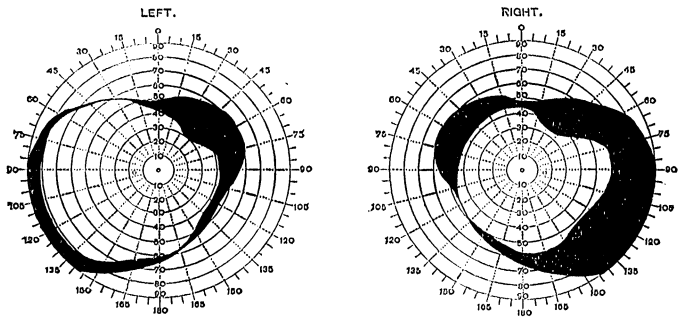
ILLUSTRATIVE CASES OF APHASIA.



BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

(Continued from p. 1022.)

CASE 5. *Word-blindness in a patient who had never learned to write; constriction of the fields of vision chiefly towards the right; no obvious word-deafness; cardiac and renal disease; death; extensive old softening in the white matter of the left occipital lobe and of the left angular gyrus, and the back part of the first temporo-sphenoidal convolution.*—This patient was seen at the out-patient department of the Edinburgh Royal Infirmary on Nov. 7th, 1888, and was carefully examined at her own home on several subsequent occasions. I have, unfortunately, mislaid the detailed notes which were made except at the time of her visit to the infirmary, but my recollection of the leading facts is quite definite. The chief point of the case is that, although the posterior part of the first left temporo-sphenoidal convolution was extensively destroyed by an old softening, there was no obvious word-deafness. I should, however, here state that I had not seen the patient for several months before her death. It is therefore possible that the cerebral softening was much more extensive at the time of death than at the date of my last examination. I merely suggest this possibility, for there was nothing in the condition of the brain after death to lead me to suppose that this was the case. The word-blindness is explained by the lesion of the angular gyrus and adjacent white matter. The lesion must have involved, at all events in some degree, the optic radiations of Gratiolet. One would therefore have expected more complete right-sided lateral homonymous hemianopsia than the perimeter chart shows (see Fig. 15); but, as I have explained in the text, there was great difficulty (owing to the inability of the patient to concentrate and fix accurately) in mapping out the visual fields. The hemianopsia was probably more complete than the perimeter chart shows. Possibly the softening had become more extensive after the perimeter measurements were made. It is unfortunate that the patient had never learned to write, but there can be little doubt that if she had been able to write there would have been agraphia, for the visual speech centre (the angular gyrus) was involved in the lesion (see Fig. 16). The notes are as follows:—"The patient was a woman, aged fifty-six years; she was seen at the out-patient department of the Edinburgh Royal Infirmary on Nov. 7th, 1888, complaining of loss of memory, inability to read, dimness of vision, and dropsy. With regard to her previous history, the patient and her friend who brought her to the hospital stated that she had suffered from her heart for the past eight years, and that she had been much worse and troubled with dropsy, cough, and shortness of breath for the past six months. A fortnight previously she suddenly lost the power of speech. This continued for some hours. She then gradually regained the power of speaking and had been able to speak well since. Since the attack her memory had been much impaired and she had been quite unable to read. She was never a good reader, and had never learned to write. At the present time the patient is suffering from general dropsy, the face as well as the feet being swollen. She is very short of breath. The heart is much enlarged and there is a well-marked mitral lesion. The urine is albuminous. As to the speech faculties, the patient appears to understand everything that is said to her and has been able to do so since the attack commenced. There was therefore no indication of any lesion of the auditory speech centre. The patient answers questions and speaks quite well. No marked defect of the motor vocal speech apparatus was detected on any of the occasions on which she was examined, but the friend with whom she lived subsequently told me that she not unfrequently made use of wrong words (paraphasia) and forgot the meanings of others. The patient is quite unable to read either letters or words (complete word-blindness). There is well-marked right-sided homonymous hemianopsia to the rough test. The fields of vision were subsequently mapped out (on Jan. 17th, 1889) by means of the perimeter (see Fig. 15). The chart shows a partial condition of right-sided homonymous lateral

FIG. 15.

Perimeter chart of the fields of vision in Case 5, taken on Jan. 17th, 1889. The patient died on May 1st, 1890.

Hosted by Google

hemianopsia, with some constriction of the left halves of the fields. The hemianopsia was probably more extensive than the chart shows, for except when the test object was quite at the outer edge of the fields the patient's answers were indefinite. She had never learned to write, consequently the presence or absence of agraphia could not be determined." On one of the subsequent examinations (the notes of which I have mislaid) the patient's friend told me that the patient understood everything which was said to her, but she did not think she understood things which were read to her. This statement seems to indicate a certain degree of word-deafness; but I could never satisfy myself that any obvious word-deafness was present. She also stated that the patient used to read her Bible night and morning, but she (her friend) did not think that the patient understood what she read. On the several different occasions on which I examined her I invariably found that she could understand spoken language and could herself make use of language (speech). But I never got her to read any question which I put to her in writing. She could read a few short printed words, such as "dog," "cat," and "hat," but made frequent mistakes in reading even these short words and in reading the alphabet. She was also very bad at reading figures. For some months before her death she was in a restless condition; her friend, who lived next door to her, said that she was "queer in the head." On May 1st, 1890, she was found drowned in the Water of Leith; she had wandered out of the house and apparently fallen into the stream.

Necropsy.—Dr. Harvey Littlejohn examined the body post mortem and kindly sent me the brain. The arteries at the base of the brain were atheromatous. An extensive area of old softening was present in the left hemisphere. It involved the white matter of the left occipital lobe, the left angular gyrus, and the back part of the first temporo-sphenoidal convolution. The exact position of the softening is shown in Fig. 16 (Sections A, B, and C), which were drawn from fresh sections of the brain. The kidneys and liver were cirrhotic. The heart was very large, the left ventricle much hypertrophied and dilated, the mitral valve considerably dilated, and the heart muscle degenerated.

CASE 6. *Marked temporary motor aphasia, word-blindness, and agraphia; optical aphasia; no word-deafness; the word "dog" written as "God," which was then read as "dog."*—This case is chiefly interesting from the facts that, while there were marked temporary motor aphasia, word-blindness, and agraphia, there was no obvious word-deafness, and that after the temporary effects of the primary lesion had passed off the patient wrote some words backwards—e.g., he wrote "God" for "dog," and after having written "God" for "dog" he read the word "God" as "dog." The notes are as follows:—The patient was a man, aged forty-two years. He was seen at the Edinburgh Royal Infirmary on Sept. 8th, 1890, suffering from motor aphasia, word-blindness, and agraphia. With regard to the previous history, he had been quite well until five days previously. On getting out of bed in the morning he felt sick, but did not vomit; he fell over three times in trying to get up. When his neighbours went into the room they found him quite sensible, but unable to speak. There was no headache and no giddiness. His condition was as follows. The patient seemed to understand everything that was said to him (the auditory speech centre did not appear to be affected). There was marked motor aphasia, almost the only words he could use being "yes" and "no." There was also marked word-blindness. When asked in writing, "Are you a fool?" he showed no sign of intelligence. When the sentence was read aloud to him he laughed and seemed much amused. There was also marked agraphia. He could not write his own name when told to do so. There was some right-sided hemianopsia. There was no obvious paralysis of the face. The right arm was much weaker than the left. The grasping power of the right hand as measured by the dynamometer was 85, and that of the left 116. In walking the right leg was dragged slightly. There was no cardiac lesion and no albuminuria. On Sept. 9th the patient's power of speaking was better and the motor power in the right arm was almost equal to that in the left. The dynamometer registered on the right 130, and on the left 135. On Sept. 10th the speech faculties were again carefully tested. The patient understood everything that was said to him. He spoke much better than on admission, but there was still a marked degree of motor vocal aphasia. Reading and writing were very markedly impaired—especially writing. He could not name a knife when it was shown to him. He read his own name correctly; but read "you" as "out" and made many similar mistakes in reading. He knew the figures "2" and "1." He could not read "42"; he said "41" was "5." He knew the individual figures "4" and "5" in "45," but he could not combine them. When asked to write

FIG. 16.

A series of transverse vertical sections through the brain, seen from the front, in Case 5 (word-blindness, but no obvious word-deafness) showing the exact position of the lesion (softening) in black. Fig. A represents the occipital lobe; Fig. B further forward at the level of the pons Varolii; and Fig. C further forward at the level of the optic thalami and corpora albicantea. The softening involves the angular gyrus (pli coubre) and first temporo-sphenoidal convolution.

"cat" he wrote "s a m a n." He could not write his own name. He wrote the letters "a" and "b" correctly when asked to do so. He could not write the letters "o" and "t." He said he was "forty-two years of age," but could not write it. He wrote "12" for "21." He could copy letters, figures, and words quite easily and correctly. On Sept. 13th he was very much better. He wrote his name and address quite distinctly. When asked to write "dog" he wrote "God," and when asked to read the word "God" which he had written read it as "dog." When told he was wrong, that he had written "God," he said, "Oh! yes, you have another way of writing it," and laughed. After an interval he was asked to read the word "God," and said, "That is very good, the name of God." On this day the patient discharged himself, and was not seen again.

CASE 7. *Case of word-blindness and agraphia; instead of reading individual letters as letters, the patient substituted a word commencing with the letter which he could not read—"George" for "G," "nearly" for "n," &c.*—The patient, a man aged fifty years, was seen on June 29th, 1893. With regard to the previous history, the patient, who suffered from free aortic disease, great enlargement of the heart, and

Hosted by Google

albuminuria, had had two cerebral attacks. The first occurred on June 15th, 1892. In this attack he became paralysed on the right side, but did not lose consciousness. Speech was not affected. The paralysis slowly improved, but still continued. The second attack occurred on April 17th, 1893. The day before the attack (April 16th) he complained of violent headache, inability to see to read, and giddiness. The next morning his wife noticed that he could not speak properly. The paralysis of the arm and leg was no worse after this attack. He had been unable to read since this attack, and only able to write very imperfectly. He looked well in the face and said he felt well. His appetite and digestion were good. His wife said that he was very restless, always wanting to be off somewhere. He himself said: "Oh, I get tired of one place; if I could only read it would not be so bad." He was much more irritable than he used to be. He walked with a slight limp. There was little or no paralysis in the right arm. The grasping power of the right hand as measured by the dynamometer was from 90 to 105, and that of the left from 85 to 90. With regard to his speech faculties, he seemed to understand everything that was said to him (the auditory speech centre was unaffected). There was no marked defect of vocal speech, but his wife said that every now and again he made use of a wrong word. For example, "I want a pint of 'matter,'" meaning "milk." "Church," "white," and "height" were great words of his; he was constantly bringing them in in wrong places. His wife said that he was all wrong about figures and names. He repeated anything he was asked to repeat correctly. He was almost completely word-blind. His wife said that he would not admit this himself. He made a point of "reading" the paper every morning, but she was sure he could not understand it. She had on several occasions noticed that he held it upside down. When tested he could not read the words "November," "Edinburgh," "thus," "house," "Edinburgh Hospital Reports"; but read the words "dog" and "hat" correctly. He was unable to read the individual letters; he said "a" was "m," "o" was "d," "h" was "10," and "p" was "d." When asked to read the individual letters he in many instances said a word beginning with that letter; for example, he said "n" was "nearly," "G" was "George," and "J" was "James." He could not read numbers. Asked to read "10," he said, "No, I don't know." There was marked agraphia. He could sign his own name; and when asked to write something spontaneously wrote, "I am getting better." He was unable to read this sentence after he had written it. He could not write "June, 1893," "Edinburgh, 1896," when asked to do so. He wrote "26" for "28." His wife said that he often did stupid things; for example, he would eat his egg with his fish-knife. Shortly after this report was written the patient died suddenly; a post-mortem examination was not allowed.

CASE 8. *Case in which right-sided hemiplegia, complete motor (vocal) aphasia, word-blindness, and agraphia (probably due to embolism of the left middle cerebral artery) were suddenly produced, but in which there was no word-deafness; slow and gradual recovery; condition of the patient fifteen years after the original accident; mirror writing, &c.*—The chief points of interest in this case are: 1. That after a severe cerebral lesion, the exact nature of which is not clear, there was complete motor aphasia, word-blindness, and agraphia, but (if the patient's statement is to be relied upon) no word-deafness. 2. That the motor vocal aphasia was only very slowly recovered from. 3. That when the patient was admitted to the infirmary, fifteen years after the original seizure, marked word-blindness, with great constriction of the fields of vision and almost complete agraphia, were still present. 4. That she was able to write her own name with the left hand in mirror writing with comparative ease; but that other words, which were written with much greater difficulty and effort, were written with the left hand in the ordinary direction (from left to right). 5. That she could read and write numbers and figures much better than letters and words. The notes of the case are as follows:—The patient, an unmarried woman aged thirty-one years, was admitted to the Royal Infirmary on April 4th, 1896, complaining of pains in the right leg and foot of two months' duration, and of old-standing right-sided hemiplegia. With regard to the previous history, the patient stated that she enjoyed excellent health until she was sixteen years of age. She then had a long illness, the exact nature of which is doubtful, but which she termed intermittent fever, and was confined to bed for seven months. During convalescence from this illness she suffered from severe frontal headache; it occurred daily and lasted for about an hour at a time. Some days after the headache commenced she suddenly became unconscious while sitting at the table getting tea; she stated that she remained unconscious for a long time (? several weeks). On recovering consciousness she found that the right side of the body was paralysed, the right side of the face, and the right arm and leg being affected, and that she was speechless. She was also unable to read, and of course unable to write. In addition to the motor paralysis there seems to have been right-sided hemianæsthesia. She stated positively that as soon as she regained consciousness she was able to understand what was said to her perfectly well. This is a very interesting and important fact. It seems to support the view that the auditory word-centre in the right hemisphere is in some persons sufficiently educated and active to carry on the function of understanding spoken language when the corresponding centre in the left hemisphere is destroyed; in other words, that compensation is more quickly and easily effected in the case of the auditory speech than the motor vocal and the visual speech centres. There can be no doubt that in this case there was a very extensive lesion on the left side of the brain. The sudden onset of the attack and the age of the patient at the time when the attack occurred (sixteen years) are strongly suggestive of embolic infarction rather than of cerebral hæmorrhage. It is difficult, too, to suppose that if the case had been one of hæmorrhage such extensive results—complete right-sided hemiplegia, motor vocal aphasia, and word-blindness—would have persisted for such a length of time. It must, however, be admitted that the long duration of the coma and the hemianæsthesia which appears to have been present were in favour of hæmorrhage or (leaving the hemianæsthesia out of account) of thrombosis rather than of embolism. Now, if the case was one of embolism or arterial thrombosis it seems certain that the blood-supply to the parts of the brain to which the middle cerebral artery is distributed must have been completely interrupted; and if this was so it is probable that the auditory speech centre was implicated as well as the visual speech centre and Broca's convolution. Although the patient stated that she could understand spoken language quite well, it did not, of course, follow that there was no defect in the action of the auditory speech centre. Déjerine, Mirallié, and others are of opinion that any severe lesion in the "zone of language"—which comprises the motor vocal speech centre (Broca's convolution), the auditory speech centre (posterior part of the first or upper temporo-sphenoidal convolution), and the visual speech centre (angular gyrus and supra-marginal convolutions), and which involves any one of these three great centres for language (say, the motor vocal speech centre)—produces some, and usually very obvious, defects in the action of the others (say, the auditory and visual speech centres). In some cases the derangement of function in the centre or centres which are not directly involved by the lesion is latent and only to be demonstrated by careful testing. It is quite possible, therefore, indeed probable, that if the faculty of auditory speech had been carefully tested in this patient at the time when she recovered from the acute attack some defect in her power of understanding spoken language would have been observed. But this does not in any way invalidate my argument—viz., that in some cases in which there is every reason to suppose that the auditory speech centre is the seat of a profound lesion, the faculty of understanding spoken speech is comparatively little affected. And if this proposition be granted, the only satisfactory explanation which I can see of the facts is that the auditory speech centre in the right hemisphere is in some degree functionally active and capable of carrying on the function of the left auditory speech centre which is destroyed. In my experience word-deafness in a complete form is less common than the other forms of aphasia. This is, I think, best explained by one or other of the following suppositions: (*a*) that the auditory speech centre is less vulnerable, so to speak, than the other speech centres—in other words, that its inosculatory circulation is more free and that complete destruction or softening of the auditory speech centre (the first, and perhaps also the second, temporo-sphenoidal convolutions), the result of embolic infarction, is consequently less frequent than complete destruction of the visual speech centre (angular gyrus) and the motor speech centre (Broca's convolution), though I am not aware that this has been

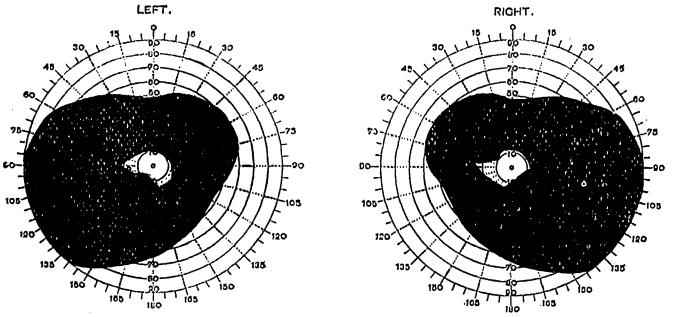
Hosted by Google

actually proved to be the case; or (*b*) that in some persons the corresponding auditory speech centre in the right hemisphere of the brain is functionally active in some degree. For the reasons given below this view is, I think, highly probable. In short, I am disposed to think that in some persons there are two more or less active (functionally educated) auditory speech centres for the reception of spoken languages—one in the left and the other in the right hemisphere (the first and perhaps also the second temporo-sphenoidal convolutions). It is difficult, I think, without adopting this supposition to explain the facts: (1) that complete word-deafness is, comparatively to the other great primary forms of aphasia (word-blindness and motor vocal aphasia), rare; (2) that recovery from word-deafness is usually much more rapid and more complete than recovery from motor aphasia or word-blindness;[1] and (3) that extensive lesions of the left temporo-sphenoidal lobe (such as softening due to embolic infarction, tumours, and abscesses) are occasionally, though probably very rarely, met with after death in cases in which there was no obvious or marked word-deafness during life.[2] Clinical and pathological observations undoubtedly show that in the great majority of persons the auditory word-centre in the left hemisphere is far more highly educated and active than the corresponding centre in the right hemisphere. Indeed, so much so is this the case that most authorities seem to think that the auditory speech centre in the left hemisphere is the only active auditory speech centre. In cases in which word-deafness persists in a marked degree (unrecovered from) for a considerable period of time before death and in which the left auditory speech centre is on post-mortem examination found to be destroyed it is obvious that the left auditory word-centre was the "driving" or active centre, and the right auditory speech centre was inactive and uneducated, or, to speak with absolute accuracy, insufficiently active and insufficiently educated to carry on the speech function which was destroyed; just as in the great majority of persons the left motor speech centre and the left visual speech centre are the "driving" or active centres. But for the reasons I have just stated there are, I think, some grounds for supposing that in some persons the auditory speech centre in the right (inactive) hemisphere is in some degree functionally active—in other words, somewhat more highly educated than the other speech centres (the visual and motor speech centres) in the right hemisphere. I am aware that, in supposing that the auditory speech centre in the right (usually inactive) hemisphere, so far as speech is concerned, is in some persons possessed of some active speech function, I differ from the usually accepted opinion—viz., that the speech centres are only active in one (the left) hemisphere. Thus Mirallié says—and his opinion represents the usually accepted opinion of the day—"le cerveau droit n'a rien à voir avec la fonction du langage."[3] With this opinion I cannot agree. Everyone admits that if Broca's convolution is destroyed in a young person the motor aphasia which results may be, and usually is, completely recovered from, and that this recovery is due to the fact that the opposite motor speech centre in the right hemisphere takes up and carries on the function of the left motor speech centre which is destroyed. Barlow's classical case completely proves this. Further, there is every reason to suppose that in young persons the same process of compensation may and does occur in the case of the sensory speech centres (auditory speech and visual speech centres). Again, it is certain that the same method of compensation, though it is far less easily established and much less perfect when established, occurs in the adult as well as in the child. Now, my argument is that this process of substitution and compensation is in many persons more easily established in the case of the auditory speech centre than in the case of the visual speech centre and the motor vocal speech centre.[4] This is only, I think, what we might expect on physiological grounds, since the auditory speech centre is first partially educated, and its action is, in most persons at all events, more automatic than the action of the visual speech centre, and possibly somewhat more automatic than the motor vocal speech centre, the action of which is to a large extent initiated, regulated, and governed by the auditory speech centre. And this supposition is, I think (for the reasons already advanced), confirmed by the effects which are produced by disease.

But to return to the details of the case. After recovering from the coma the patient remained speechless and unable to read and write for a very long time. The facial paralysis was recovered from in the course of a few weeks; some motor power was slowly and gradually regained in the right arm and leg. She stated that she was almost speechless for seven months and that the power of speech was then very slowly and gradually regained. It was only during the past two or three years—that is to say, it was not till twelve or thirteen years after the attack—that she had been able to speak with anything like facility. The power of reading was regained more slowly still, and since her illness she had not made any effort to write. Ever since the attack she had been more or less delicate and had had repeated attacks of bronchitis. Four years ago she suffered from congestion of the lungs. About five years ago there was some skin eruption on the forearms, apparently psoriasis. With regard to the family history, her father died from congestion of the lungs, chronic bronchitis, and ague; her mother from typhus fever; and a sister in childbirth. She had two brothers and four sisters alive and well, but one brother had had three attacks of rheumatic fever and another brother was for a long time troubled with rheumatism, while a sister was also much troubled with chronic rheumatism; in fact, the patient said that a large number of her near relatives had been rheumatic. She did not know if any of them had ever suffered from heart disease. The patient was well nourished and appeared to be in good health. She still walked with a slight limp, and the right arm and hand were still markedly paralysed. Both knee-jerks were exaggerated, the left even more so than the right. Ankle-clonus could also be elicited in the left leg. The pain in the right leg and foot of which she complained was apparently the result of muscular spasm or cramp; it was increased by walking and when pressure was made on the ball of the great toe. She also said that it was worse in damp and changeable weather. The grasping power of the hands, as measured by the dynamometer, was in the right 15, and in the left 50. There was no perceptible difference in the muscular power on the two sides of the face. The right arm and leg were smaller than the left. The detailed measurements were as follows: The right arm at the thickest part, 13¾ inches; the left arm at the thickest part, 12 inches; the right forearm at the thickest part, 9¼ inches; the left forearm at the thickest part, 9¾ inches; the right thigh at the thickest part, 16¾ inches; the left thigh at the thickest part, 17¼ inches; the right calf at the thickest part, 12 inches; and the left calf at the thickest part, 12¾ inches. The right hand was smaller and more delicate looking than the left; the fingers were slightly flexed, and the thumbs were slightly drawn into the palm. There was no perceptible difference in the tactile sensibility on the two sides of the body. The fields of vision were markedly constricted in each eye (see Fig. 17). As to the speech functions, the patient was mentally quite bright and alert and seemed to understand everything that was said to her. The only apparent defect in motor speech was a difficulty in pronouncing long words—"Constantinople" for example. She could sing a little; after the attack she lost the power of singing for a time, but it had gradually come back to her. Her reading was very defective. Before the onset of the hemiplegic attack she was a good reader and good writer. She said herself that now she could hardly read anything and that she could not spell at all. She read her own name, the words "dog" and "hat," and the individual letters of which they were composed; also the letters

[1] In my experience word-deafness is more easily recovered from than motor vocal aphasia, and motor vocal aphasia than word-blindness. The order of recovery, be it observed, is that in which the speech faculties are trained and developed.

[2] Possibly the relative rapidity with which word-deafness is usually recovered from explains, in some measure at least, its apparent rarity; possibly word-deafness is more common than my own observation would lead me to suppose, the aphasic defect being, in some cases at least, recovered from before the patients come under observation. It must also be remembered that until quite recently the true nature of cases of marked word-deafness was often unrecognised. Such cases were not unfrequently, and they, perhaps, are still occasionally, thought to be cases of insanity, or of ordinary deafness (as distinct from word-deafness), or of motor aphasia.



[3] De l'Aphasie Sensorielle, p. 93.

[4] I am disposed to think that in some persons the visual and motor vocal speech centres in the right hemisphere may also be active in some slight degree, and that, in young persons at all events, when the active or driving centres in the left hemisphere are destroyed they (the visual and motor vocal speech centres in the right hemisphere) may become active in a high degree.

Hosted by Google

"e," "o," "m," "b," "s," "n," and "w" correctly. She could read numbers and combinations of numbers much better than letters and combinations of letters (words). Her power of spelling was very defective. Asked, "What is your name?" she gave it correctly. When asked, "How do you spell it?" she replied, "Cannot." When asked to spell her Christian name, she spelt it correctly. When asked to spell her surname, she replied, "Don't know." Asked what was the first letter she replied "M"; the second letter, she replied "Don't know." She continued to say "Don't know." She soon got tired with reading; she reads, she says, much better to herself than she can read aloud. She knew and named correctly a knife, key, watch, and a button-hook after some hesitation; she did not know a tuning-fork (apparently because she had never seen the object before), and said, "Oh! that is a doctor's thing"; in short, there did not appear to be any optical aphasia. She could copy letters

FIG. 17.

Perimeter chart of the fields of vision in Case 8, showing marked constriction of the peripheral portions of the fields in both eyes.

with either hand. She wrote her name with the right hand. When asked why she could not spell it she said sharply, "Well, because I did not know; other things I cannot spell; wrote it just out of my mind." She wrote the word "dog" as "doy," and said, "But mind, I'm no' donnert" (daft). She wrote "o" with the left hand, and "b" after looking at it, with the left hand as "a." On April 6th she read, "Are you very old?" and the numbers "10," "200," and "58" correctly. She named pieces of money (a halfpenny, a shilling, and a threepenny-piece) at once without any hesitation. When asked to write the word "cat" she wrote "c" and said, "You see, I have lost all my spelling. Well, I cannot make that." She could not write "God" two minutes after she had copied it. She wrote her own age (thirty-one) correctly. She wrote her names correctly with the left hand in mirror writing, also the word "cat" with the left hand in mirror writing; "54" in the usual direction with the left hand, and "37" and "hat" in the usual direction with the left hand. Asked to write down how she felt she said, "Oh! I cannot." Asked to write down the word "dog" with the left hand she said, "Oh! I could not; don't know how to spell." On April 21st she wrote her names in mirror writing with the left hand; and "God," "cat," and "dog" (doy) with the left hand in the ordinary direction. The power of writing was tested on several subsequent occasions, with the result that she invariably wrote her name with comparative ease (apparently automatically and without much effort) with either hand; but it was always written with the right hand in the usual direction (from left to right), and always written with the left hand in the reverse direction (in mirror writing), whereas other words which she had great difficulty in writing, and which were only written very slowly with much effort and thought, were almost invariably written with the left hand in the ordinary direction (from left to right), and with the exception of the word "cat," as stated above, never written in mirror writing.

(To be continued.)

BATH AND SOMERSET SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS.—At the annual meeting of this society, which was recently held in Bath, it was stated that legacies amounting to £315 had been received in 1896, but the expenditure had exceeded the income by £36.

BATHS AND GYMNASTICS IN ARTERIO-SCLEROSIS.

BY MEDICINALRAT J. GROEDEL, M.D.,
BAD-NAUHEIM.

FOR many years I have devoted great attention to the treatment of arterio-sclerosis, and on several occasions have published the results of my experience, which, however, may not have come to the knowledge of the majority of English physicians. For this reason, and because so much interest has been shown of late by medical circles in England in the balneological and gymnastic treatment of heart diseases I have felt induced to discuss the above subject in an English medical journal. I shall begin with the treatment by baths. The first question is, "May any person whatever with demonstrable arterio-sclerosis, or where such may with probability be assumed, be allowed to take baths?" The increased pressure of blood which is considered the usual consequence of treatment by Nauheim baths may at first sight seem to indicate that every patient with arterio-sclerosis should be excluded from a treatment by baths. A further increase of the high blood-pressure usually found in arterio-sclerosis[1] must not only surcharge the heart more than is already the case, but also create the danger of the bursting of a cerebral miliary aneurysm, so often present in cases of arterio-sclerosis. I have, however, by numerous observations been able to convince myself that baths can be prescribed for these patients in such a manner that the increase of blood-pressure does not take place, or only in a very slight degree. If the temperature be kept almost at the point of indifference, that is, about from 92° to 93° F., the primary acute increase of blood-pressure caused by the contraction of the cutaneous vessels, and most to be feared, will be very slight, and if there be carbonic acid in the bath at the same time will quickly disappear. If the skin of the patient be cooled somewhat by moistening the parts particularly sensitive to cold before entering the bath, the avoidance of that primary increase of blood-pressure, or, indeed, any shock whatever, will be the more certain. A similarly good effect is produced when the patient is only allowed to take half-baths and the exposed parts of the body are wrapped up so as to prevent cooling. In most cases the amount of water can be increased little by little at each bath until a full bath is at length attained, but even then it is advisable to let the patient only submerge his body by degrees, and placing cold bandages on the bather's head is often indicated. By proceeding cautiously in this manner I have never had an unfortunate case in the course of a practice of twenty-two years in Nauheim. Under what conditions can a course of baths be indicated or beneficial in cases of arterio-sclerosis? It may be desirable to give baths for some other disease when arterio-sclerosis is present. It is mostly a question of diseases based on the same etiological principle as arterio-sclerosis itself, or such as usually lead to it. By combating these we can at the same time retard the progress of the sclerotic process in the vessels. I will only mention gout, chronic articular and muscular rheumatism, arthritis deformans, and neurasthenia.

That it is possible completely to remove existing sclerotic degeneration by any means I do not believe; we are, however, undoubtedly able to retard (aufzuhalten) the deleterious process. The first thing is, of course, the removal of all conditions disposing to arterio-sclerosis. One of these, for which treatment by baths is especially serviceable, I have already mentioned. Of the greatest importance is a proper diet and general regimen, to which the patient must be trained, and this is easier and more successful in a watering-place than at home. But even a direct influence of the baths on the sclerotic process, and with it a limitation of the disease, is in my opinion possible. When I consider all the

[1] Basch considers that every permanent super-normal blood-pressure (more than 150 mm. Hg at the radial artery) is to be considered a sign of arterio-sclerosis, even when there are no other symptoms. He calls this "latent arterio-sclerosis."

Hosted by Google

theories that have been propounded regarding the origin of arterio-sclerosis, I come to the conclusion that a disturbance in the nutrition of the walls of the vessels must play an important part, and that functional troubles of the vascular innervation are perhaps the primary cause. The acknowledged tonic effect of the baths on the nervous system may, of course, be taken into especial account for the vaso-motor part of the process. Disordered nutrition in certain organs can no doubt be entirely removed, or at least improved, by means of baths; why not also disordered nutrition of the vascular system?

Of particular importance is a course of baths in cases of arterio-sclerosis, when owing to this change the heart is no longer able to satisfy the increased claim on its functional capacity. So much has been written of late years about the tonic effect of carbonic acid thermal baths on the heart that I need not enter further into this subject. I shall content myself with stating that with disordered circulation also, when this is caused by arterio-sclerosis, the manifold consequences of cardiac insufficiency, if recent, sometimes disappear, and if more advanced can often be decidedly improved. We find not infrequently that in the course of a "kur" the pulse improves considerably as regards frequency, quality, and rhythm. On examination the heart also shows a corresponding change for the better compared with its former state. Yet there are cases enough in which the success is only a slight one, especially those in which the arterio-sclerosis has attacked the greater vessels in a more extensive manner or has even led to a dilatation of the aorta and aortic regurgitation; then, again, little success is attained in cases in which there is already an advanced degeneration of the myocardium. In such cases we may be satisfied even with a little success. Baths are contra-indicated for arterio-sclerosis when there is such a high degree of insufficiency of the cardiac muscle that digitalis and the other usual drugs remain without any effect. For patients with remains of apoplexy the following rules may be laid down. If apoplectic fits have already occurred repeatedly every kind of bath treatment must be avoided. After the first attack six months at least must pass before a course of baths is prescribed, so as to be to a certain extent sure that there is no tendency to recurrence. For those persons, however, whose apoplectic fit has occurred more than a year previously a course of baths may be prescribed without any misgiving whatever. In cases of sclerotic contraction of the kidneys (as well as of contracted liver in cirrhosis), according to my experience, treatment by baths is of little use, both as regards the sclerotic process in these organs and the secondary disturbances in the organs of circulation which are dependent on it. For patients of this class who are very much enfeebled baths are absolutely contra-indicated. The same may be said when arterio-sclerosis is combined with diabetes, if patients are very much enfeebled. But if there be no great weakness patients usually feel very well during a course of baths of not too severe a character, if a corresponding mode of life be observed. Patients with aortic aneurysm should only be advised to take a course of baths when the disease has assumed a more stable character. In the course of years I have treated a comparatively large number of such patients. I have usually observed a decided improvement in their general state of health, and likewise in the state of their circulation, without ever having had an unpleasant incident to record. As regards angina pectoris following sclerosis at the commencement of the aorta near the origin of the coronary arteries, or sclerosis of these arteries themselves, I may state that I have seen many patients with all the appearances of angina pectoris take a course of baths with very good results; but others have derived no advantage from it whatever, or only very little. That in the cases first mentioned I had always to deal with true angina pectoris (sclerotic) I will not venture to maintain.

The mechanico-gymnastic treatment is of less importance for arterio-sclerosis than the baths, and can only be applied to a limited extent. A gentle, not too prolonged, general massage is almost always permissible; likewise passive movements may be employed, as thereby only relief of the heart is brought about without any incitement to the energetic output of force and without any increased blood-pressure. As regards the circulation of the blood itself, the result is not usually very great, whereas for the above mentioned diseases that often accompany arterio-sclerosis, such as rheumatism and gout, massage is often beneficial. Resistance gymnastics cannot be allowed in cases of universal arterio-sclerosis of a high degree. The increased energy of the heart action caused by the muscular exercise is only compensated in an incomplete and unsatisfactory manner by a corresponding dilatation of the arteries, and therefore a dangerous raising of the blood-pressure and surcharging of the heart takes place. Instead of an improvement of the cardiac insufficiency in such cases, the opposite is brought about; whereas if the arterio-sclerosis be not advanced or be apparently confined to only a few vascular regions an attempt with resistance gymnastics may be made, but gymnastics must be very gentle—that is, the exercises should be made with little resistance and all trying movements avoided. For this purpose I prefer the Swedish manual gymnastics as modified by the late A. Schott, and which I have made use of since the publication of his first paper on this subject (1881). The mildest form of these manual resistance gymnastics resemble passive gymnastics very much in effect. The incitement to venous discharge from the capillary regions and the peripheral veins, as well as the easing of the arterial current—that is, relief of the heart—surpass by far the increase of the cardiac action which is caused by motor impulse and other circumstances. As regards the so-called Zander mechanical gymnastics for these patients, only those apparatus can be made use of which serve for passive movements, massage, or vibration; yet in exceptional cases some other apparatuses are applicable.

It is a matter of course that patients who have once had apoplexy are not to be treated by resistance gymnastics, nor those patients affected with aneurysm. Some may think the same applies to angina pectoris, but in this disease I have sometimes seen a good result produced by resistance gymnastics. Whether in these cases it was a question of sclerosis of the coronary arteries or not is difficult to say. I can only state that the patients showed unmistakeable signs of arterio-sclerosis. Of course, in these cases, too, the movements must be of the easiest kind, and must be desisted from altogether, as previously explained, if the peripheral arteries are very rigid.

Some patients feel greatly benefited by vibrations applied to the back by Zander machines. Last year I had a patient under treatment who was able to cut short the attacks of angina pectoris by applying vibration to the cardiac regions with a small special apparatus. I must, however, here caution the reader not to regard what has been stated as universally applicable. We must in each case, cautiously feeling our way, try whether gymnastics can be borne, and if there be the slightest doubt we must desist.

Now a few words about the "Terrainkur" (pedestrian exercises). Many patients with arterio-sclerosis complain of oppression even while walking up gentle ascents; but sometimes we hear that such patients feel very well while walking slowly up-hill; however, as a rule, I should not advise methodical hill climbing to be used therapeutically for persons with arterio-sclerosis. Fifteen years ago it happened that a patient with angina pectoris under my treatment while attempting to climb a hill near Nauheim, in spite of my having forbidden it, fell down dead. I have been obliged to express myself very briefly, so as not to exceed the space at my disposal, and have especially avoided, as far as possible, all theoretical views and physiological explanations. My chief aim has been to give some useful hints and advice to the profession, relying upon a large experience gained during many years' practice, and I hope thereby to have been serviceable to some.

Nauheim.

AN ARTIFICIAL LARYNX.

BY T. P. ANDERSON STUART, M.D. EDIN.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF SYDNEY, NEW SOUTH WALES, AUSTRALIA.

THE patient for whom I contrived this artificial larynx was a man who had had his larynx removed, on account of carcinoma, by Dr. A. MacCormick at the Prince Alfred Hospital, Sydney, on Jan. 31st, 1895, and was brought under my notice by Dr. MacCormick in the end of the same year. The wound had duly healed, leaving the tracheal opening, in which the patient wore a soft rubber tracheotomy tube with a soft rubber shield, and leaving also above the tracheal opening a small fistula opening into the pharynx. Between these two openings was a wide groove not deep enough to

Hosted by Google

contain an apparatus of any size. Further, the patient had a deal of chronic bronchitis, and so frequently coughed up a copious tough secretion that any of the artificial larynges I had read of or had seen figured appeared to me to be quite unsuited to his case, owing to the ease with which secretions could lodge on the reed and so silence it. Moreover, in all such instruments, as, for instance, Gussenbauer's or its modifications, where respiration and phonation take place through the same channel, if that channel is large enough for respiration it is too large for phonation, and if it is small enough for phonation, then it is too small for comfortable respiration. Further, where respiration and phonation are through a common opening the reed may sound during ordinary breathing—a most objectionable feature when present. This was recognised by Heine,[1] and Heine accordingly made the reed so that it could be moved aside during respiration—that is, it was in position only when required to phonate. I therefore determined to start on what appeared to be new lines—to make an instrument with which the patient's breathing should be free and unrestrained, and with which therefore he should not habitually breathe through the reed opening, in which the reed should be brought into play only when he desired to phonate, and which, being protected from the secretions of the air and food passages, should continue to act all day long, even during meals. It also appeared desirable that no metallic part should anywhere come into contact with the tissues. It is, moreover, obviously of the greatest importance that the patient should himself be able to apply the instrument, to remove it and to clean it easily. The instrument should also be comfortable to wear and thus willingly worn. All of these conditions were fulfilled by the instrument to be presently described, so that the patient himself applied it and wore it all day long, even during meals, and removed and cleaned it himself. I mention these points somewhat prominently, because from the figures—for I never saw an artificial larynx until I had made one—I should say that, at all events, some of these larynges were anything but comfortable to wear, even if they were efficient as phonators. Indeed, comfort in the wearing of such instruments is almost as important as their efficiency as sound producers, because the patient will very soon lay them aside if they are not comfortable. Further, the flexibility of its parts and the ease with which their exact shape and dimensions can be modified to permit this larynx to be adapted to almost any conceivable case, for each case has its own peculiarities, and, moreover, it requires no very skilled workman to make it, so that it can be made almost anywhere, since there are few places where one cannot find a clock- or watch-maker or a jeweller. As a matter of fact, I have availed myself of such materials only and of such workmanship as may be had in any part of the world almost. This, however, is a distinct advantage, for cases requiring the application of substitute larynges are not so common that in practice the artificial substitutes can be kept in readiness for possible cases.

Hitherto, when speaking of the clogging of the reed, I have had in view mainly the tracheal secretions, but in truth the mouth secretions may be very copious. The difficulty has been recognised and has been met by a lid in Gussenbauer's larynx[2] to act like a little epiglottis, on the theory that the epiglottis acts like a lid, a theory, however, which we have shown to be incorrect.[3] In other modifications of Gussenbauer's larynx an obturator[4] is used; in others a cork or a plug of cotton-wool (Czerny), and so forth. In my instrument the difficulty is entirely got over; no saliva escaped down the pharyngeal tube, and the patient swallowed his meals without any, even liquid, food coming down; but further, even it had come down, it would have been very easy to get rid of it before it touched the reed. I had one larynx made with such a provision (see Fig. 5, *g*), but since I eventually found that it was unnecessary I omitted it in the final form. In Gussenbauer's form the reed can readily be removed and replaced for the purpose of being cleaned, and I fancy that, owing to the secretions and coughing, this will often require to be done. By the protection afforded to the reed in my instrument the necessity for removing it is abolished. I did make a form in which the reed was removable, but I abandoned it when I found that the provision was not needed. Obviously the more simple one can make such things the better—so long as they act efficiently, and of this there can be no question at all in the case of the instrument now under description. The tone of the voice produced was, I dare say, monotonous, as, indeed, has been described in connexion with other instruments of the sort; yet the word monotonous conveys rather a false impression, for although modulation in the sense of varying the pitch of the sound produced within the artificial voice-box was not possible, yet the resonating chambers, by variously reinforcing the fundamental tone and its overtones, did introduce a sort of modulation or timbre which prevented the voice from being quite without character. The patient's family, for instance, told me that in the new voice there was a distinct reminder to them that their father was speaking, with a voice much altered of course, but still with much of the character of the old voice. The reeds which I used were of the commonest. I merely cut into segments the reed-plate of a common mouth-organ; each segment was a reed and the lowest pitched ones were used—viz., d, e, and a. Owing to the untimely death of the patient from scurvy I had not an opportunity of trying other than these reeds, otherwise I should have tried the non-metallic reeds of ivory, horn, cane, and vulcanite which Foulis[5] says he found to be better than the metallic. The modified Gussenbauer's larynx, with the lobster-tailed tracheal and pharyngeal tubes figured in Jacobson[6] shows that the desirability of having the tubes flexible had already been recognised. In the "International Encylopædia of Surgery" already quoted similar devices are said to have been made by von Bruns and by Caselli. In truth, judging from what I saw in my own case rigid unyielding tubes would have been most comfortable. Even the lobster-tailed tubes however, cannot have been so comfortable as the ones I adopted. First, with regard to the tracheal tube, of necessity the patient wears a rubber tracheal tube from the time of the operation, so that by the time he is ready for the substitute larynx he is quite accustomed to the rubber tracheal tube. My form of the larynx, then, is simply inserted into the mouth of this, his ordinary tracheal tube, and nothing new to him is introduced, so that the application of the artificial larynx did not at all worry the patient.

In regard to the pharyngeal tube, it must fit the fistula, or fluids will come down by the side of it, keeping the neck of the patient and the mouth of the tracheal opening continually wet. The size of the tube will vary with that of the fistula, but as the latter is more or less under control (of this more later) it is as well to keep it small, the outside diameter of the tube being a little over 6 mm. It should be quite flexible in every direction transversely, but at the same time rigid longitudinally when compressed, so that it may be pushed into the fistula, and in the movements of the head and neck run no chance of kinking, while at the same time it freely yields to these movements. It should likewise be incompressible laterally, so that no pressure of the muscles or other parts can occlude it. Rubber tubing does not meet these conditions unless the wall be very thick, but in that case the lumen of the tube is very small, considering the size of the tube externally. Further, I found that the valve which I adopted at the upper end of the tube was with difficulty fixed to the rubber. My first successful pharyngeal tube was the vein of an ox hardened in 2 per cent. solution of alum for forty-eight hours. The vein was supported by a closely wound spiral of piano wire half a millimetre thick. The outside measurement of the coil was 6 mm. The coil ended in a less closely wound cupola, at the apex of which the wire was turned into the interior of the whorl, so that it could not injure anything. The vein being left projecting about one-third of an inch beyond the apex of the wire coil, air could pass upwards freely, though fluids could not pass into the tube downwards. The cupolar ending of the coil prevented the wire from cutting the vein, kept the vein from being inverted into the interior of the coil, and gave a more or less pointed end for introducing the tube into the fistula. The wire was not closely wound at the cupola, and thus permitted the air to escape without obstacle. The vein, however, proved too fragile—the wire tore it during the act of introducing it, the movements of the pharynx tore it over the cupola, and the warmth and moisture softened it and made it useless. I then tried tubes of silk, cotton, and thin leather, but finally found perfect satisfaction in winding

a strip, 12 mm. wide, of sheet rubber a quarter of a millimetre thick, such as is used by dentists, slightly on the stretch, obliquely around the wire coil, with its edges slightly overlapping so as to make a continuous tube. The wire coil has, as it were, a spiral bandage of rubber applied to it. The more the rubber is stretched during its application the more unyielding is the resulting tube. If the rubber available is very thin one may have two layers, and in that case one would commence below and wind upwards, and then return winding downwards to the base-collar, to which the rubber is then made fast by a thread. When only one layer of rubber is used one had better begin to wind it above, the upper end being fixed by winding one or two turns, one over the other, before commencing to descend. The valve at the upper end of the pharyngeal tube is made of a piece of suède or kid leather and is absolutely efficient, for while when wet it readily permits the sound-bearing air to pass into the pharynx it quite prevents anything from passing down into the artificial larynx, so that the patient wore the apparatus the livelong day. The valve is attached to the wire coil by a loop of thread around a part of the coil, where two or three turns of the wire are soldered together, so that the thread has no chance of separating the wire turns. The free part of the valve is from 12 to 15 mm. long. At its lower margin it is covered by the rubber, so that there is an easy transition from the surface of the rubber to the leather, and the rubber helps to bind the valve to the wire coil. Before introducing the tube into the fistula the valve should be wetted and rolled between finger and thumb or folded upon itself lengthwise, so that it becomes a sort of point to the tube. The patient may wet the tube with saliva as a lubricant, and while it is being pushed in it should be rolled round its long axis to help its progress. Coughing not unfrequently is excited when the tube enters the pharynx, but in my case it very soon ceased. It is of importance that the pharyngeal tube be neither too long nor too short, for if too short the force required to drive the air through it is too great, while if it be too long it irritates the pharynx and gets in the way in swallowing. To measure accurately the length required I fixed to the base collar a small flexible rubber tube about one and a half feet long; the other end was in my own mouth, and by blowing I kept up a steady air pressure while the tube was passing up the fistula. When the air passed quite freely I marked the length of tube within the fistula, and adding a little extra to allow for movements of the parts I took this as the length of the tube to be ultimately adopted. When the leather wears out the valve can be easily replaced. Placed as I was at the Antipodes, I had, as already said, to work with the materials to be had on the spot, and I accordingly used sheet brass from ½ to 1 mm. thick, soldered at the joints. Owing to their non-corrosibility, gold plate and vulcanite would have been good materials in which to make the permanent form. Further, it might be advantageous to have a sort of hood on the front of the rubber shield to lodge and cover the artificial voice-box, partly to protect it and partly to make it inconspicuous, though owing to its small size this larynx was not very noticeable. I once went along a crowded street with the patient wearing the larynx and hardly anyone noticed him.

The pharyngeal fistula in this case was the upper end of the original wound, so that the line of the cicatrix extended downwards from the fistula. As it was found that the presence of the tube seemed to stretch the cicatricial tissue and dilate the fistula unduly, the fistula was by a subsequent operation closed, and at the same time a new opening in sound tissue was made just below the hyoid bone. A small rubber tube closed at the upper end was kept in the new opening until granulation was complete, and the pharyngeal tube now inserted gave entire satisfaction. I may mention in passing that the epiglottis was absent. At this stage the question was raised whether it would not be desirable when practicable to close the œsophageal wound at the time of the first operation. The pharyngeal opening for the artificial larynx could be made at the same time or subsequently. Meanwhile, the closure of the gullet would prevent the escape of fluids which is such a source of trouble and danger. Should another opportunity of performing the operation present itself Dr. MacCormick proposes, immediately after stitching the trachea to the edges of the skin, to bring together the edges of the mucous membrane of the alimentary canal and secure them with interrupted sutures of catgut, and then to bring together and secure in like manner the edges of the skin with sutures of horsehair. Feeding would thus be from the first by tube through the nose or the mouth, so as to avoid interference with the œsophageal wound, and when the time came for the fitting of the artificial larynx an opening—if not already made at the time of the first operation—would be made just below the hyoid bone, and either in the middle line or to the side, according to circumstances. In the event of the new opening for the pharyngeal tube being made at the time of the first operation the new opening might be made use of to feed the patient by pumping the food through a fine catheter.

Points which the foregoing description may not have made clear will most likely be understood on reference to the figures. Fig. 1: The artificial larynx before its tracheal tube *a* is inserted into the rubber tracheal tube, as seen in Figs. 10 and 11. The hood *b* widens the inferior opening of the larynx; owing to this enlarged inferior opening the

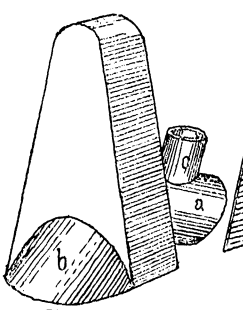

Fig. 1.

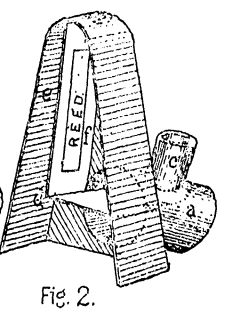

Fig. 2.

escape of the air in expiration is made so easy that very little of it passes upwards through the passage *d* to the reed, and thus the reed does not sound except when the inferior opening is closed during phonation. The closure being effected by grasping the larynx between finger and thumb (the finger on the apex of the larynx and the thumb over the inferior opening), the closure is rendered more easy by filling the right angles of the inferior opening with solder, as is seen in Fig. 4. The complete septum between the butt of the pharyngeal tube *e* and the tracheal tube *a* is partly indicated by a dotted line in Fig. 2, but is seen best in Fig. 3. The arrows in Fig. 3 and Fig. 5 show the direction taken by the air during phonation. Fig. 2: The larynx with front removed, showing the opening *d* leading out of the inferior chamber of the apparatus into the chamber *e*, whence the reed opening leads into the chamber *f*, which now leads into the pharyngeal tube *e*. These relations are seen also in Fig. 5. Fig. 3: A vertical and antero-posterior section. The dotted parts of the arrows are within the chamber *e*. The lower arrow passes through the opening *d* and the upper arrow through the reed opening. The course of the air in phonation is thus *a*, *d*, *e*, *f*, *e*. Fig. 4: The larynx as seen from below. The space *g* is in the simpler form of the apparatus a part of the general inferior opening, but where the chamber *f* is drained, as in Fig. 5, the space *g* is the lower end of the drain; in that case the dotted line alongside *g* in Fig. 5 is a solid septum,

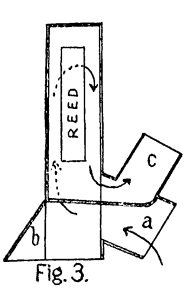

Fig. 3.

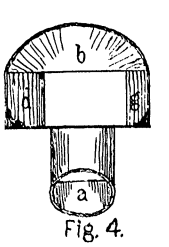

Fig. 4.

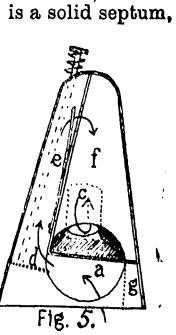

Fig. 5.

and the septum between *a* and *f* is wanting above *g*. By the filling up of the posterior angles of the wide inferior opening of the instrument closure by the thumb in phonation in more easily accomplished. Fig. 5: A vertical transverse section. This figure shows two modifications which may perhaps be useful in particular cases, though neither was needed in my case. The opening *d* may be closed by

Hosted by Google

the valve shown when, in violent coughing, secretion is forced up into the chamber *e*. This valve is depressed when the larynx is grasped by the finger and thumb during phonation, and it is raised again by the spiral spring shown around its stem. The chamber *f* may be drained by the channel *g*, if it is found that secretions get into the chamber *f*. This channel also is closed by the thumb in phonation. Figs. 6, 7, 8, and 9 show the pharyngeal tube and its parts;

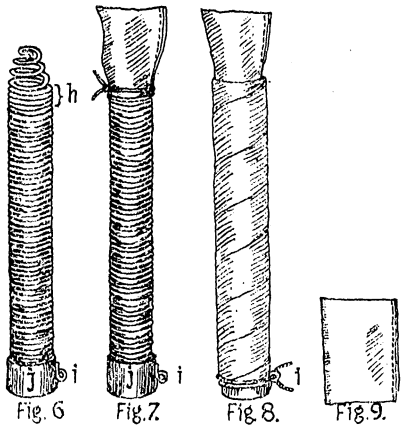

Fig. 6 Fig. 7. Fig. 8. Fig. 9.

the wire collar is soldered to the brass collar *j*, which fits upon the butt of the pharyngeal tube *e*. The three turns at *h* are soldered together, so that the leather valve, Fig. 9, may be tied upon the coil here. The turns in the dome are somewhat widely separated, so as to offer less resistance to the sound-bearing air. The end of the wire is turned within the dome, so that it cannot injure anything. The end of the

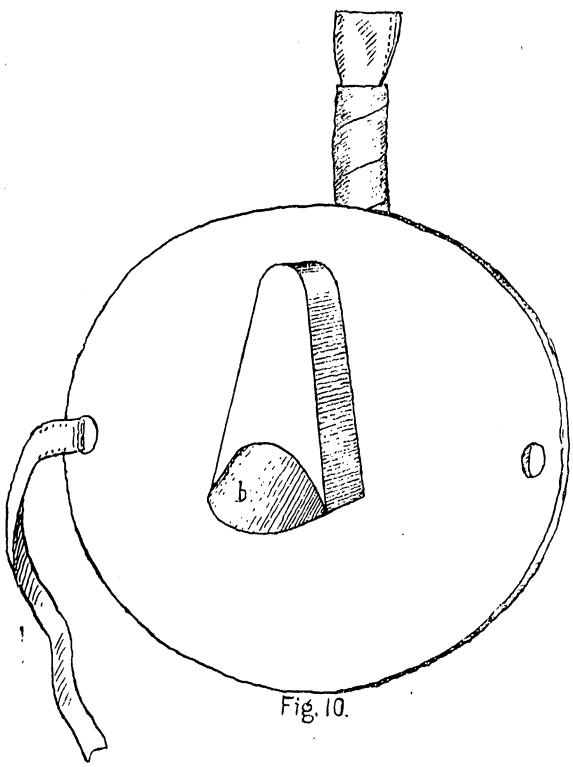

Fig. 10.

thread by which the rubber bandage is secured to the brass collar is brought through the ring *i* and then round the tracheal tube as in Fig. 11, so that the whole is secure. Figs. 10 and 11: Almost a full face view and a full profile view of the entire apparatus fitted up ready for use. The obliquity of the tubes *c* and *a*, as shown in Fig. 3, enables the

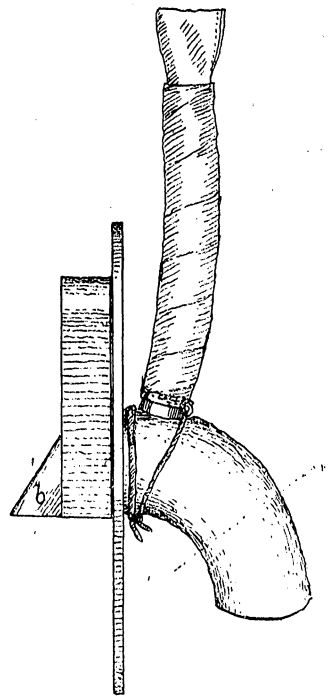

Fig. 11.

larynx to accommodate itself to the direction of the pharyngeal and tracheal openings.

Sydney, New South Wales.

ON CERTAIN SYMPTOMS OF SPINAL CORD AFFECTION IN BICYCLE RIDERS.

BY EDWARD SEMPLE, M.D. BRUX., L.R.C.P. EDIN.,
LATE SURGEON TO THE BLANDFORD COTTAGE HOSPITAL;
AND
JAMES TAYLOR, M.A., M.D. EDIN., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEENS-SQUARE, AND PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

WE have recently been associated with Dr. Hughlings Jackson and Dr. Cayley (to both of whom we are much indebted for suggestions in reference to the present paper), and also with Dr. Voelcker and Dr. Colman, in the care and treatment of a patient suffering from myelitis, in whom the first symptoms—numbness in the perineum and loss of muscular sense in the legs—came on very soon after hard bicycle riding. This case has been the means of directing our attention to the possible association in other cases of symptoms indicating an affection of the nervous system with bicycle riding. The case of the patient referred to above we are not at liberty to publish at present, but we are able to give an account of a case of a similar nature which has been under treatment in hospital.

CASE 1.—The patient was a young man, who had had a chancre, but no sore-throat or skin eruption, and had otherwise enjoyed good health. He was in the habit of riding a bicycle daily and he rode as hard and as fast as he could, and after getting home he not infrequently lay in a draught to cool himself. After some months he found that he had numbness in the penis and perineum, and that during connexion he had no sexual sensation although there was emission. He still continued to use his bicycle, but he then began to have difficulty with his legs, first with the right and later with the left, and he found that he

Hosted by Google

could not feel the pedals of his machine as he rode. He then had incontinence of urine, and he also found that he had no sensation when he passed a motion. There was now also much adductor spasm in the legs, so that they sometimes became crossed, and remained so until forcibly replaced with the hands. He became unable to walk unless supported on either side, and he had difficulty in lifting the feet, the toes (especially of the left foot) seeming to cling to the ground. There was no wasting of the muscles or change in electrical reactions. The knee-jerks were exaggerated and ankle clonus was present on both sides. There was diminished sensation above the knees, and the sense of position as regards the left foot was lost. His condition gradually improved, so that he became able to walk without support, although there was some unsteadiness, which was chiefly manifested when he stood with his feet together or when in walking he suddenly turned round. His gait was markedly spastic, and the knee-jerks were still exaggerated and ankle clonus was present. There was no impairment of sensibility and he had regained to some extent control of the bladder, although he had no sensation in the urethra when he passed urine, and he had neither erections nor emissions.

This, then, was the case of a man, otherwise apparently strong and healthy, in whom impaired sensibility in the penis and perineum and loss of sexual sensation succeeded hard bicycle riding, and to these symptoms were superadded others which pointed unmistakeably to an affection, probably a slight diffuse myelitis, of the lateral and posterior columns of the spinal cord.

CASE 2.—The next case that came to our knowledge was that of a strong and healthy man, aged thirty-two years, who mentioned in conversation that some years ago, after a long bicycle ride, he experienced a sensation of coldness, numbness, and tingling in the penis. On being recently questioned he repeated the above statement, and in reply to a question said that he did not feel the urine pass if he micturated within some hours after a long bicycle ride, and that he then had to look to see when the stream of urine stopped, having no knowledge of its cessation unless he did so.

CASE 3.—Another patient seen by one of us was a man who spent his last autumn holiday on a bicycling tour. He stated that he experienced numbness, cold, and "pins and needles" in the penis and perineum after riding, and he also noticed that when bicycling, instead of being, as he usually was at other times, regular in his bowels, he never had any call to stool. He went as usual, however, but he passed his motion without any of the ordinary sensations.

In all these cases, apparently, a similar condition existed—viz., a sensation of numbness in the penis and perineum, and loss of sensation during the passage of urine and motions for some hours after riding. We have also heard, through a woman whom they themselves informed, of two sisters, enthusiastic bicycle riders, who habitually experienced numbness in the perineal region after riding, and total loss of sensation when passing urine, this loss persisting for several hours. In Case 1, however, although similar symptoms were present, others were superadded, indicating a more serious condition—viz., an actual affection of the spinal cord. It is not unlikely that in all of them there was produced, presumably through pressure, some condition of the nervous structures subserving the perineal region, possibly analogous to that which obtains in pressure palsy or crutch palsy. It is possible that in the case in which the spinal cord became most involved this condition became an actual neuritis, and that the inflammation spread so as to set up a similar process in the spinal cord. It is a well-known fact that after an operation for hæmorrhoids there may be temporary retention of urine, and in a case mentioned by Mr. Jonathan Hutchinson[1] there was, following such an operation, complete permanent paralysis of the sphincters of the bladder and anus, an effect probably of a localised destructive lesion in the spinal cord. It is probable that a similar mechanism was effective in the case mentioned of myelitis which was preceded by numbness in the perineum.[2]

The matter seemed to us to be so important, in view of the wide prevalence of bicycling as a sport and as a pastime, that we have thought it well to publish these facts without insisting too much upon the connexion of the more serious conditions with bicycle riding. The association is certainly very suggestive, but it will be well to await further evidence before definitely regarding one as the cause of the other. There is no doubt that whatever inconvenience or danger may exist can be altogether avoided, or at least minimised, by attention to the saddle and to the attitude assumed by the rider. One man whom we interrogated informed us that he used to experience sensations similar to those described by the patient in Case 3 until he had adopted a different method of pedalling, what we believe is called the "push and draw stroke," which also necessitates an upright posture, with the weight thrown well back on the ischial tuberosities. There can be little doubt that the attitude in which the rider leans forward over the handle-bar is one in which pressure will be exerted on parts which ought to be free from it. It is also obvious that a saddle or handle-bar which in any way conduces to such a posture is a source of danger. There are other effects of a bad saddle and an unsuitable attitude in the saddle, such as tenderness, swelling, and actual inflammation of the external genitalia, of which two instances have come under our notice. These, however, are outside the scope of this paper, in which our object is to direct attention to the occurrence in certain cases of not only slight, but also severe, affections of the parts of the nervous system specially related to the perineal region and the lower limbs, in association with the use of the bicycle.

[1] Illustrated Medical News, Jan. 26th, 1889.

[2] We have been informed that one who was a well-known professional bicycle rider a few years ago had always to have his urine drawn off after a hard race. Our informant, however, had no actual knowledge of the facts.

NOTES ON ONE YEAR'S SURGICAL WORK.

BY HORATIO P. SYMONDS, F.R.C.S. EDIN.,
SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.

THE following paper contains the notes of the hospital work done by me during the year from Sept. 23rd, 1895, to Sept. 23rd, 1896. The number of cases under each head is given and any remarks as to history or treatment that may be of interest have been added. I have carried out the modern aseptic surgery in as strict a manner as possible, and I append the directions which I supply to nurses in charge of my abdominal cases as illustrating how the principles of these modern methods are applied by me in a particular group of operations. For the notes of the cases I have to thank Dr. F. G. Proudfoot and Dr. W. L. Fry, the house surgeons during the period covered.

1. *Radical cures of hernia.*—Eight in number. Operation by Macewen's method, the age of the patients ranging from three years upwards. The patients laid on their backs for six weeks.

2. *Operations for necroses of bones.*—Five in number.

3. *Radical cure of hydrocele.*—Five in number. The method adopted in each case was this: An incision was made over the tumour varying from one inch to two inches in length. The fluid contents were evacuated. The anterior wall of the sac was excised, and then the edges of the skin wound were brought together. No drainage was used.

4. *Osteotomy.*—Five cases. These included two cases of genu valgum and three cases of bowed tibiæ. The method used in the former was that of Macewen's, with the difference that for the chisel a saw was substituted. In the latter cases a small incision was made over the tibia, which was sawn through at the position of the greatest curvature.

5 *Flat foot.*—Four cases. The method adopted in two of these cases was as follows. The metatarso-phalangeal joint of the great toe was excised, and the ends of the bones were brought in apposition and kept there by silver wire loops. By this means the inner aspect of the foot was shortened and a permanent arch was formed.

6. *Kidney.*—The first kidney case died from immediate shock, after a prolonged and difficult operation of removing the remains of a suppurating kidney from which on a previous occasion several calculi had been removed. After the removal of the kidney more calculi were found within, which could not be removed until the kidney was taken away. The second kidney case—a suspected hydro-nephrosis—died from suppression of urine ten days after operation. The kidney was much damaged mechanically in an exploratory operation.

7. *Bronchocele.*—Five cases. In one of the cases, that of a young girl, the cyst was simply drained. The anterior

Hosted by Google

wall of the sac was removed and the edges were sutured to the margin of the wound. It continued to discharge for several months, but the last report from the patient stated that the wound had closed up. In the other cases one lobe of the gland was removed. The incision in one case was the ordinary longitudinal incision, in the remainder a transverse incision was employed. In the course of the operation each bloodvessel was clamped with pressure forceps and not ligatured till the tumour was removed. In this way the dangerous part of the operation—viz., the removal of the tumour—was quickly got over, and the wound toilet was performed leisurely. In each case the operation was done because of urgent dyspnœa. In one case, that of a woman, there was subsequent delirium for five days.

8. *Acute abscess requiring incision.*—Four cases.

9. *Abdominal section.*—Four cases. (*a*) A girl, aged twelve years, was admitted because her mother affirmed that she occasionally passed blood in her urine. On examining the abdomen a small tumour about the size of a walnut was felt in the lower part of the abdomen. It was decided to cut down on this. There was no blood in the urine on admission. When the child was under the anæsthetic the tumour was noticed to have disappeared, and to find out what had caused this temporary swelling a small incision was made over the region of the bladder, when the tumour was found to be an abnormally large uterus. This was examined carefully, and apart from its size nothing abnormal was seen. Two days after the operation the patient passed per vaginam a small body about the size of a walnut, which on microscopical examination proved to be a myoma. She made a perfect recovery. The blood mentioned by the mother as coming with the urine was doubtless from the uterus. (*b*) This was a case of severe gall-stone colic in a man, aged thirty-four years, but with no jaundice. A stone was felt near the origin of the cystic duct, but on manipulation it returned into the gall-bladder. (*c*) This was a case of pyonephrosis, with persistent discharge of pus after several operations for removal of calculi had been performed, each time with the removal of calculi. The kidney was found to be merely a sac, with no kidney substance, and firmly bound down by adhesions. No attempt was made to remove the kidney. (*d*) This was a case of prolapsus uteri in a woman, aged forty-seven years. The uterus had been prolapsed for three years and had been treated by means of pessaries with no benefit. The following operation was performed: An incision was made as for oöphorectomy. Each ovary was removed, together with about one inch of the broad ligament. A transverse incision was made through the rectus muscle on each side, and the stump of the broad ligament was brought up and sutured to the division in the rectus on each side. The stump was thus embraced by the rectus muscle and the uterus was drawn well up into the abdomen. The woman made an excellent recovery, and there was no evidence of any prolapse.

10. *Middle-ear disease.*—Three cases.

11. *Amputation of fingers.*—Three cases.

12. *Post-pharyngeal adenoids.*—There were three cases in which post-pharyngeal adenoids were curetted. The method of administering chloroform was to bring the patient only half under its influence and while operating to have the head of the patient well over the end of the table.

13. *Epithelioma of the lip.*—Three cases. One patient, an old man aged seventy years, with very extensive growth, died. After the first operation some of the sutures gave way, leaving a gap. He was anæsthetised a second time for the purpose of dividing the cheek to relax the tension. This was done, but he died somewhat suddenly a few hours after from cardiac failure.

14. *Bursa patellæ.*—Two cases.

15. *Hysterectomy.*—Two cases. (*a*) This operation was performed through the abdomen, the patient being a woman, aged thirty-nine years. There was a history of a swelling in the abdomen for six years, which had increased rapidly within the previous twelve months. On admission the abdomen was found to be much distended, the measurement round the umbilicus being thirty-seven and a half inches. A diagnosis of fibro-cystic tumour of the uterus was made. At the operation an incision, at first three inches long, was made below the umbilicus, and afterwards enlarged to within one inch of the ensiform cartilage. The tumour was found to be incorporated with the uterus. The whole was removed with the exception of the stump of the uterus. The patient recovered well from the operation. Death occurred seven days afterwards from exhaustion following acute intestinal obstruction. Post mortem the bowel was found to be adherent to the stump of the uterus. (*b*) This operation was one of vaginal hysterectomy, the uterus being removed by the method recommended by Martin of Berlin, as follows: The cervix was fixed by volsellum forceps and the uterus was pulled well down. The mucous membrane was divided at the junction of the cervix and anterior fornix. A finger was introduced and the ureter and bladder were pushed well out of the way. The peritoneum was cut through and the fundus of the uterus was grasped and pulled down into the vagina along with its appendages. Both broad ligaments were ligatured and the whole was removed. No attempt was made to suture the peritoneum to the vaginal mucous membrane. The patient, beyond a slight attack of pneumonia, progressed satisfactorily, and left the hospital well one month after the operation.

16. *Varicose veins.*—Two cases. The veins were marked before operation and two tiny incisions were made on either side of the vein, a flat blunt handled needle with ligature attached was passed in at one incision under the vein and out at the other incision, and the needle withdrawn. It was then re-inserted unthreaded at the point of the first incision, being this time passed over the vein and out at the second incision. The needle was then threaded with the end of the ligature and both were withdrawn and the ends of the ligatures were tied. This was done in several places as often as was considered necessary.

17. *Excision of the tongue.*—Two cases. This operation was performed by Whitehead's method, both patients being able to leave the hospital within a fortnight.

18. *Periostitis of the ulna.*—Two cases treated by incision.

19. *Epithelioma of the jaw.*—Two cases, in which the submaxillary glands were involved. In one case the jaw, with the glands, was removed, and the patient left the hospital considerably relieved. The other case was one with extensive involvement of the glands. No attempt was made to remove the jaw, but several of the glands were removed, as they were causing the patient great pain. He left the hospital free from pain, but he has since died.

20. *Tuberculous abscess of the hip.*—Two cases, in which the head of the femur had previously been removed, and one case in which there was no marked disease of bone. Improvement was great in each case.

21. *Scirrhus of the mamma.*—Two cases, in which the breast and glands were very freely removed.

22. *Curettage of the uterus.*—Two cases.

Operations Performed Once.

23. Bad union of both bones of the forearm after fracture above the insertion of the pronator radii teres.

24. Amputation at the hip joint for sarcoma of the head of the femur.

25. Extensive scalp wound.

26. Loose semilunar cartilage, which was removed.

27. Dilatation of the cervix uteri for dysmenorrhœa causing epileptiform fits. The patient was under observation for several months, but there was no recurrence of fits.

28. Ingrowing toe-nails.

29. Adenoma of the breast.

30. A case of abscess behind the sigmoid flexure of the large intestine. The patient, a boy aged fifteen years, was admitted with symptoms of acute intestinal obstruction. There was a history of his having eaten large quantities of walnuts. His temperature on admission was 100°F. After frequent enemata, with a purgative pill containing aloes, cascara, and nux vomica, his bowels were moved freely five days after the constipation had set in. The temperature, however, still kept high, and on further examination tenderness was made out in the left iliac region, with definite fluctuation. An incision was made over this region and a large quantity of fœtid pus was evacuated. A fæcal fistula was diagnosed two days afterwards. The patient for six weeks hovered between life and death, his condition at one time being aggravated by basal pneumonia. Several fæcal stones were removed at the end of the fifth week, and thereafter the patient immediately began to improve. The wound ceased discharging and the boy rapidly became quite well. He remained in hospital for three months.

31. Amputation of the penis for epithelioma of the glans.

32. Urethral caruncle excised.

33. A case of ovarian cyst. In this case there was a history of abdominal swelling for three years and the cyst had been tapped on four occasions. At the operation the cyst was found to be multilocular. Forty-one pints of fluid were evacuated. The cyst was adherent in several places

Hosted by Google

to the peritoneum. In separating the adhesions part of the anterior layer of the peritoneum was stripped off. The patient recovered well from the operation, and for seven days went on without a bad symptom. At the end of that time, however, symptoms of peritonitis set in, and the patient died. At the necropsy the peritoneum was found to be adherent in several places.

34. A case of empyema in which the pleural cavity was drained, after the removal of two ribs, for six weeks. Eventually the lung expanded to a considerable extent, and the patient recovered.

35. Aural polypus removed by torsion.

36. Case of Tagliacotian skin-grafting after an extensive burn. There was marked contraction at the elbow and wrist. The skin was freely dissected up from the elbow and the arm fixed to a raw surface on the breast for three weeks. The result was entirely successful as regards the raw surface on the wrist, but some contraction at the elbow remained.

37. Urethro-vaginal fistula for torn urethra after labour.

38. A case of ruptured urethra which after several operations made a very good recovery. The case was complicated by the addition of a fractured femur.

39. Erasion of the knee-joint for tuberculous disease in a child. The patella tendon, with the tubercle of the tibia attached, was turned up, the joint was exposed, and all the diseased tissue was removed.

40. A case of imperforate anus.

41. A case of papilloma of the neck.

42. A case of inguinal colotomy for intestinal obstruction, from which the patient died. At the necropsy a large gall-stone about the size of a small hen's egg was found obstructing the small intestine. At the operation no distended intestine was found, though a small piece of the small intestine seemed rather inflamed, but there was no exudation upon it.

43. A case of lupus.

44. Removal of sebaceous cysts.

45. Excision of glands of the neck.

46. A case of gall-stones in which there had been a history of gall-stone colic and jaundice for three years. On opening the peritoneum the liver presented, but no gall-bladder was seen. On passing the hand in a large gall-stone was felt under the surface of the liver. This was removed, and was found to be of the size of a pigeon's egg. The edge of the gall-bladder could not be brought to the surface of the wound. A glass tube was put into the gall-bladder and packed firmly round with sterilised gauze pads. Eventually a tract for the bile formed shut off from the peritoneal cavity. The patient continued to improve, and left the hospital with no bad symptom, the jaundice having entirely disappeared and the stools containing bile.

47. A case of transverse fracture in which the patella was wired. The patient walked with the aid of crutches in ten days. He returned after two weeks with pain in the joint. The silver wire was then removed. In six weeks from the accident he walked about with only a slight limp.

48. Removal of fatty tumour from the shoulder.

49. Division of the tendons of the sterno-mastoid for wry-neck.

50. A case of tuberculous meningitis in which the cerebellum was trephined. The trephine entered just below the occipital protuberance. Some cerebro-spinal fluid escaped. The patient improved for two days, but gradually sank and died.

51. A case of pyosalpinx, in which the ovaries and Fallopian tubes were removed.

52. A case of rectal polypus.

53. A case of hammer-toe.

54. Amputation of the thumb.

55. A case of rodent ulcer.

56. Excision of epitheliomatous glands of the neck.

57. Hæmorrhoids removed by Whitehead's operation.

58. A case of ruptured perineum.

59. A case of hare-lip.

60. Perineal section for extravasation of urine, in which the patient made a good recovery.

61. A case of spina bifida, in which the tumour was opened and the cauda equina found in the centre. This was separated and placed in a trough cut out of the tissue on the sacrum. A portion of the parietal bone of a recently killed rabbit was sutured over the opening in the sacral canal. The patient died.

62. A case of intestinal obstruction by Meckel's diverticulum. The band was found at the operation and divided, but there was evidence of peritonitis then, and the patient died from peritonitis two days after the operation.

63. A case of dermoid cyst of the ovary, which was felt per vaginam and diagnosed as a prolapsed ovary. The patient had been treated for years for malposition of the uterus. The patient made an excellent recovery.

64. There were two cases of amputation at the hip-joint, one being for tuberculous disease of the joint. The patient made a good recovery. The other was in consequence of a sarcoma of the head of the femur. The patient recovered well from the operation, but died five months later from secondary growths in the lungs. The causes of the nine deaths which thus occurred were as follows: (1) obstruction by a gall-stone in the small intestine; (2) excision of the kidney; (3) ovariotomy, adherent peritoneum; (4) fibro-cystic tumour of the uterus, adhesion between the intestines and the stump of the uterus; (5) epithelioma of the lip, heart failure after the second operation; (6) nephrectomy; (7) trephining the cerebellum, tuberculous meningitis; (8) spina bifida; and (9) intestinal obstruction by Meckel's diverticulum.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, PLAISTOW.

FATAL CASE OF PURPURA HÆMORRHAGICA AND PEMPHIGUS OCCURRING IN A RICKETY CHILD.

(Under the care of Mr. ERNEST A. T. STEELE.)

WHATEVER may have been the etiology and the exact pathology of the case recorded below, it cannot be doubted that a great morbid change had taken place in the blood. It is in some respects very suggestive of "scurvy-rickets," but it certainly does not readily fit into the classical descriptions of cases of that disease.

A female child, aged four years, was admitted into the hospital on July 1st, 1896, with the history that she had never been a healthy child, did not walk till late, and, as the mother said, had "always had rickets." Her diet for a considerable time past had consisted entirely of milk and farinaceous foods. Her present illness began on the evening of June 26th, when she seemed to be poorly and had a slight cough. On the 27th her nose bled a good deal and her gums slightly. On the 29th she developed a papular eruption on the face and limbs and was drowsy. The eruption was scanty and of a dark rose colour, but there were no vesicles or bullæ. On admission into the hospital her condition was as follows:—On the left side of the forehead and left cheek, the right cheek, and both arms and legs there were numerous purple patches varying in size from a sixpence to a five-shilling piece, and in the centre of many of these patches there were large circular bullæ containing dark-coloured serum. (When a photograph was taken eight hours after death the bullæ had collapsed and one over the left orbit had burst.) Both wrists and ankles were swollen, and the child cried if moved. Her temperature was 103° F. and her pulse was 130. There was considerable bloodstained discharge from the nose, but the gums were not bleeding. During the day she passed a small quantity of very dark-coloured urine which, however, could not be saved for examination. She was very restless all day and her breathing became very hurried. The temperature rose to 106° at 10 P.M. At 1.30 A.M. on July 2nd she became very drowsy, had a slight rigor, and died comatose at 2 A.M. At the necropsy, which was made twenty-four hours after death, the main lesions discovered were innumerable small hæmorrhages into the lungs and a decolourised blood-clot in the right heart,

Hosted by Google

which was distended, the left heart being empty and contracted; there was a decolourised clot filling the superior longitudinal sinus. The organs were otherwise healthy. The bones were soft and porous, and the ends of the ribs were enlarged.

Remarks by Mr. E. A. T. STEELE.—The above case appears to me to have been an advanced type of scurvy-rickets, the most noticeable points in the diagnosis being the history, the long-continued farinaceous diet, and the swelling of the wrists and ankles in the neighbourhood of the epiphyses of the tibiæ and radii. The complication of pemphigus is unusual and difficult to explain. Dr. Sansom has reported[1] a case of purpura hæmorrhagica associated with acute pemphigus, but this was in a girl aged twelve years and was a sequence of influenza.

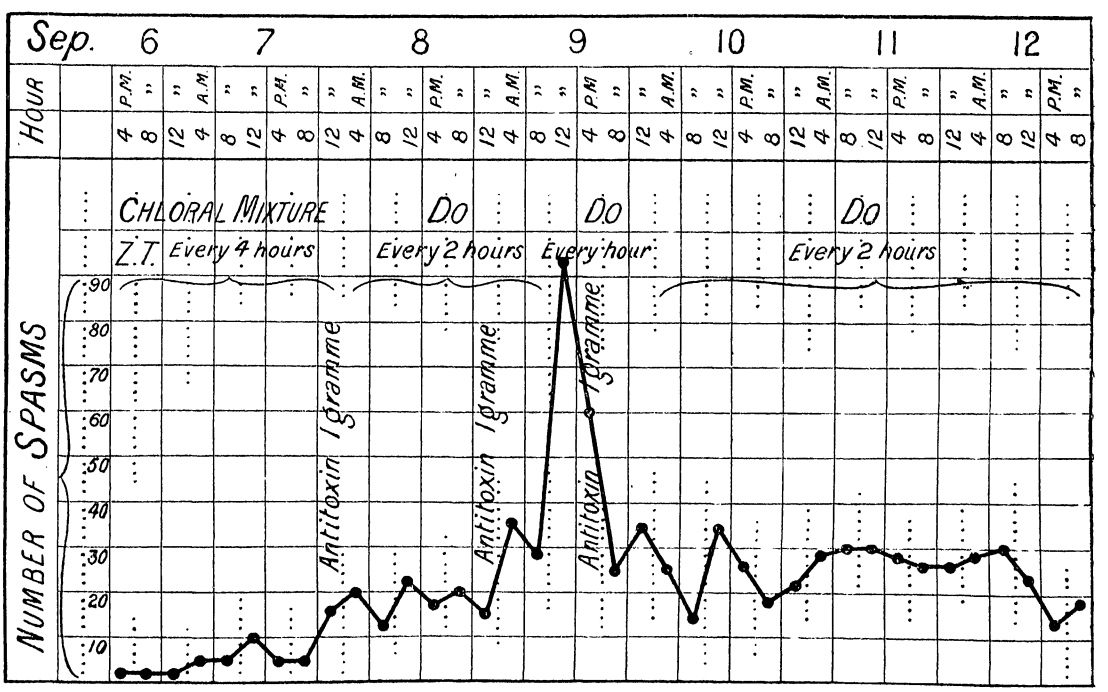
THE AUCKLAND HOSPITAL, NEW ZEALAND.

TWO CONSECUTIVE CASES OF TETANUS TREATED WITH TETANUS ANTITOXIN AND CHLORAL HYDRATE; RECOVERY.

(Under the care of Mr. ARTHUR MARSACK.)

ALTHOUGH the value of tetanus antitoxin is very generally acknowledged, yet it cannot be said that we are at present fully possessed of exact indications either as to the quantity to be administered or as to the cases in which it is likely to be really beneficial. In many cases, and those not necessarily very severe, but little benefit seems to follow its employment, while in others the improvement is striking and enduring. Under these circumstances it is highly desirable that all those cases of tetanus should be put on record in which the antitoxin has been thoroughly tried. The following two cases are noteworthy in that chloral was extensively used as an adjuvant, and the value of this drug in symptomatic treatment by controlling the spasms is often very marked. For the notes of these cases we are indebted to Dr. J. C. Pabst, assistant medical officer.

CASE 1.—A lad, aged fifteen years, was admitted to the hospital on the afternoon of Aug. 13th, 1896. He was able to give the following history. On Aug. 1st, whilst walking barefooted, he trod on a piece of glass and cut his right foot. He continued to limp about, and a few days later squeezed some "matter" out of the wound, after which it rapidly healed. On the 5th during a game of football he had a severe fall, but was well enough to continue the game. Next day he went to school, but returned early as he did not feel well. For the next two days he was able to walk about, but did not feel well, and noticed especially a pain in the right hip. On the 9th he noticed that he continually bit his tongue, but though he still had pain in the hip he did not go to bed. There was no change till the morning of the 11th, when he felt too ill to get up; he "felt stiff" in places, especially in the neck, jaw, and legs. In the evening he got up, but shortly afterwards his body becoming "stiff all over" several times, he went back to bed, and passed a very restless night. On the evening of the 12th he was seen by Mr. Marsack, who found him with marked trismus, profuse sweating, and severe clonic spasms. He prescribed belladonna and a purgative, and ordered his removal to the hospital, which was done next day. On admission his temperature was 102·2° F., the pulse 120 and feeble, and the respirations were 22. The tongue was slightly coated and dryish; it was protruded with difficulty. He was mentally clear and very cheerful. There was profuse sweating. There was trismus, the incisor teeth being separated only to the extent of half an inch. Marked risus sardonicus was present. The pupils were equal, a little dilated (belladonna), and reacted sluggishly to light. He lay on his back with his knees slightly flexed. The abdomen felt like a board and the muscles at the back of the neck were very rigid. There was opisthotonos, so that the hand could be easily placed between the back and the bed. The muscles of the thighs and legs were rigid, but those of the upper extremities were quite flaccid. He could flex and extend both arms and legs. There was apparently no loss of power and no loss of sensation. The cutaneous reflexes were greatly exaggerated. The patellar reflexes could not be made out owing to the rigidity of the limbs. He was able to swallow. The heart's action was rapid. The lungs were normal. He complained chiefly of pain in the right hip. On the sole of the right foot there was a small scar in which a small splinter was buried; this latter was immediately removed. The urine was turbid, acid, of specific gravity 1030, and showed a large deposit of urates, but no albumin. The examination was frequently interrupted by short severe spasms. Five grains of calomel were immediately given, and at 3 P.M. one gramme of antitoxin (the dried form from the British Institute of Preventive Medicine) was injected into the subcutaneous tissue of the upper abdomen on the right side. During the next five hours the number of spasms, which had been thirty-six, steadily lessened, until from 7 to 8 P.M. there were only seventeen to the hour. At 8 P.M. another gramme of antitoxin was injected into the left upper abdomen. The lump raised by the first injection had not entirely disappeared, and pressure on the spot caused pain and gave rise to a spasm. At 11 P.M. the patient seemed very drowsy, but his sleep was disturbed every few minutes by a severe spasm. At 12 midnight the spasms still continued, and the prospects of a good sleep appeared bad; he was given a tablespoonful of the chloral mixture, and one gramme of antitoxin was also injected. During the next two hours the number of spasms became reduced to nine and seven respectively; however, as his sleep was still much disturbed the dose of chloral mixture was repeated at 2 A.M. on the 14th. Between 5 and 7 A.M. there were no spasms at all. At 10 A.M. the physical condition of the abdomen, neck, and face was precisely the same as on admission. At 12 noon one gramme of antitoxin was injected, and until 4 P.M. the spasms gradually increased in number and severity. There was considerable difficulty in swallowing. During the night he was delirious and tried to get out of bed. On the 15th, at 9 A.M., he was given two doses of chloral mixture and a suppository containing a quarter of a grain of morphine. His tongue was very sore from his biting it. The respiration was very laboured and noisy, especially during sleep. He was continually bathed in sweat. The trismus, risus sardonicus, and board-like abdomen remain unaltered. At 8 P.M. the question of continuing the use of antitoxin or not was discussed. It was decided to continue, for although no apparent beneficial effect could be detected, neither could it be said that the case was aggravated by its use. One gramme was therefore injected. At 12 P.M. another gramme of antitoxin was injected. The patient slept well during the night after a dose of chloral. At 9 A.M. on the 16th the bowels were well opened by five grains of calomel. Three of the points of injection were very red and tender. At 12 noon one gramme of antitoxin was injected (last dose). From this time till 9 P.M. the patient became much worse, the spasms being so numerous and the opisthotonos so marked that the chloral mixture was given, improvement immediately following. The antitoxin was now discontinued, as it was felt that the bad symptoms which followed so quickly upon the last dose might in some way be due to it. During the next two days the patient's condition remained practically unaltered. The trismus, sardonic grin, and rigidity of the muscles of the abdomen and legs were quite well marked. Chloral was pushed at night so as to secure sound sleep, and discontinued during the day, a dose, however, being given whenever the spasms became so frequent as to cause great distress, and the result was uniformly satisfactory. On the 19th there was an urticarial rash on the chest, abdomen, and back. Four of the points of injection looked angry and the glands in the right axilla were tender; however, as the temperature was not above 99° they were not opened. The body was covered with sudamina. On the afternoon of the 20th the pain in the right hip suddenly increased in severity, so much so that a quarter of a grain of morphine suppository did not give relief and had to be repeated. On the 21st, at 12 noon, as the bowels had not been open for nearly forty-eight hours, an enema was given, a scanty motion resulting. Immediately afterwards the patient was seized with a severe spasm in which the respiratory muscles were involved, the cyanosis being marked. Similar but less severe fits occurred frequently during the afternoon, and his temperature rose to 102·6°. Five grains of calomel were given, and five minims of tincture of digitalis were added to the chloral mixture. The patient passed a very bad night; he was delirious, and had numerous severe spasms. Another morphia suppository (one quarter of a grain) was given. During the next three days the patient appeared to be better, although the tonic rigidity persisted. On the 25th, from 9 P.M. to midnight, there were ninety-nine spasms. Two doses of chloral mixture were given, and the spasms rapidly



[1] Report of a meeting of the Clinical Society, THE LANCET, June 2nd, 1894, p. 1375.

Hosted by Google

subsided. All medicine was discontinued for four days, only one dose of the chloral mixture being given daily. The patient was allowed solid food on the 29th. On the 31st there was still a little trismus, and the muscles of the abdomen and neck were rigid, though less so than formerly. The lumps formed at the point of injection were much smaller and showed no signs of inflammation. The urticarial rash and sudamina had entirely disappeared. On this date the patient was removed to the general ward as a convalescent. Up to this stage of the case the temperature and pulse had been taken every four hours and the urine measured and tested daily. The temperature during the first week averaged 100°, only once touching 101°. The pulse varied directly with the temperature and ranged usually between 100 and 110. No relation could be detected between the use of the antitoxin and the condition of the muscles or between it and the temperature and pulse. The quantity of urine was fairly constant and averaged fifty ounces daily; there was never any albumin. The patient took his food well, averaging six pints of fluid daily. On Sept. 5th he was able to walk about the ward, and on the 11th he was discharged.

CASE 2.—A boy, aged four years, was admitted to the hospital on Sept. 6th, 1896, at 2 P.M. His mother dated the illness from Sept. 3rd, though she noticed that for a week previously to this he had not taken his food so well and appeared to have a "cold." However, on the date mentioned he was seized with severe "screaming fits," during which he clenched his teeth and bit his tongue. In the intervals he was unable to open his mouth widely and sweated profusely. The "fits" increasing in frequency and severity he was on Sept. 6th taken to Mr. Lewis, one of the honorary surgeons of the hospital, who recommended the patient's immediate removal to the hospital. On admission the patient was found to be a well-nourished and very intelligent child, but he refused to protrude the tongue for fear of having it bitten. His temperature was 98° F., the pulse 96, and the respirations were 32. He was sweating profusely. There was slight risus sardonicus. He could only separate the incisor teeth to the extent of one-third of an inch. There was slight rigidity of the muscles at the back of the neck, but the sterno-mastoids were unaffected. The abdomen was quite lax and there was no rigidity of the extremities. The cutaneous reflexes were exaggerated, but the patellar reflexes were absent. There was very little difficulty in swallowing. The heart and lungs were normal. The pupils were equal and reacted to light. The urine was acid, of specific gravity 1032, and contained neither sugar nor albumin. The patient was immediately placed in a warm bath, after which he was given a powder containing ten grains of calomel and five grains of compound scammony powder, also a drachm of the chloral mixture, the latter to be repeated every four hours. So far the case differed little from one of simple trismus, and although a minute examination was made no sign of a wound could be found. During the night the patient slept for six hours; and at 9 A.M. on the 7th his physical condition was unaltered; the nurse reported nine spasms. On the 8th, at 1 A.M., one gramme of antitoxin (British Institute of Preventive Medicine) was injected, as there was no longer any doubt about the condition; the abdomen was board-like, the muscles of the neck were very rigid, the risus sardonicus was much more marked, and at frequent intervals there were severe clonic spasms which threw the body into a condition of opisthotonos. A powder containing three grains of santonin and five grains of compound scammony powder was given, to be followed by a drachm of castor oil, repeated if necessary. The dose of the chloral mixture was doubled. At 9 A.M. it was noted that there had been sixty-nine spasms in the twenty-four hours. At 11 P.M. one gramme of antitoxin was injected. By 9 A.M. on the 9th the patient's condition was much worse, he lay practically on his head and heels, and the slightest touch precipitated a spasm. The bowels had been opened thoroughly and one motion contained a round worm. At 4 P.M. one gramme of antitoxin was injected. By 9 A.M. on the 10th the patient had had 252 spasms, the majority being very mild. The condition of tonic rigidity of the body remained unaltered. The increase in the number of spasms followed rapidly the last dose of antitoxin. During the next three days the patient improved; the spasms were less frequent and less severe, and the rigidity of the muscles of the abdomen and neck was less marked, though the trismus and risus sardonicus appeared to be unaltered. On Sept. 14th there was an urticarial rash on the abdomen. By the 16th the rash had almost disappeared, but two of the lumps raised by the injection were very discoloured and tender. On the 21st the patient was removed to the general ward as a convalescent. During the whole illness the temperature was very little above normal; the urine, though tested daily, never gave evidence of albumin. The patient was always able to take his food. On the 1st he was discharged. He was able to walk, though the abdomen was still a little rigid.

CASE II – CHART SHEWING SPASMS.

Hosted by Google

Remarks by Dr. PABST.—The foregoing cases complete a list of eleven cases of tetanus treated at this hospital during the past two years. Of the other nine cases (all of which passed through my hands as house physician) seven died and two recovered completely. In five of the cases the patients died within forty-eight hours after the onset of tetanic symptoms. These five cases were definitely traumatic; by this I mean that at the time they came under observation there was an unhealthy wound to be seen. These cases were treated with chloral hydrate, eserine, and morphine, combined with local treatment by the application of carbolic acid to the wound. In two other cases one patient died on the fifth and the other on the sixth day after the first symptoms appeared. Both these cases were indefinitely traumatic—one following a "gumboil" and the other a scratch on the foot; they were treated with chloral hydrate and eserine. The remaining two patients who recovered were both treated with chloral hydrate and bromide of potassium. One was definitely traumatic, following twelve days after a wound of the knee caused by a fall upon a piece of glass; the other was apparently idiopathic, as there was neither history nor trace of any wound. These eleven cases as regards their acuteness fall naturally into two groups:—1. The five rapidly fatal cases which may be taken as examples of acute traumatic tetanus, their severity depending not so much upon the shortness of the incubation period (the most rapidly fatal case of all having an incubation period of twelve days), but upon the rapidity with which the spasms followed one another, and so exhausted the patient. 2. The six sub-acute (fairly severe) cases in which the symptoms after first showing themselves developed slowly. To this group belong the two cases treated with antitoxin and chloral. They were therefore not of the severest type, and it will be noted that both cases had shown symptoms for three days before admission—a period in which the cases belonging to Group 1 had all ended fatally. Still, it would seem that sometimes after the first signs there is a period of quiescence, after which the symptoms reappear with increased severity; this would appear to be what occurred in Case 2, where for the first twenty-four hours after admission there was little else than trismus, after which the symptoms assumed the severest type. Having indicated the type of case (an essential point), it only remains to try to form a correct estimate of the value of the remedies used to bring about the successful result. A difficulty arises in that there are undoubtedly two factors—antitoxin and the chloral mixture. The effect of the chloral mixture had been studied in the two patients mentioned who recovered under its use; it lessened the number and severity of the spasms, and when pushed procured sleep. When given with the antitoxin its beneficial action was quite as apparent; after giving it improvement was expected; if none occurred the dose was increased gradually, and always with the required result. With regard to the antitoxin no improvement at all could be detected after its use; there was nothing comparable to the improvement seen to follow an adequate dose of diphtheria antitoxin in a case of diphtheria. On the other hand, in both cases the injection of the antitoxin was sometimes (not always) followed by aggravation of all the symptoms. Still, the duration of the two cases treated with antitoxin and chloral was much shorter than those two treated with chloral alone, the general prostration was less, the stage of convalescence was shortened, whilst the acute stage was about the same length. In this respect there is some resemblance to diphtheria in which a case sufficiently bad to be treated with antitoxin often convalesces more rapidly than a case which has been so mild as not to require antitoxin. This shortening of the course of the disease was to my mind the most marked feature in both cases and must be ascribed to the antitoxin. On the whole, though both these cases might possibly have recovered under chloral alone, I believe that the antitoxin was of value probably in the way of preventing the rapid development of severe symptoms; that it shortened the course of the case I feel certain. Some other points require notice. In using the antitoxin the directions issued with it were carefully followed. A rather turbid fluid was the result, and the lump raised by its injection served as a source of peripheral irritation. For this reason a more potent antitoxin would be an improvement and is more called for than in the case of diphtheria. The urticarial rash was probably a direct result of the antitoxin, but not so the sweating, which was equally profuse on admission, and, moreover, was a marked symptom in the fatal cases in which the patients did not have antitoxin. I have come to the conclusion (1) that moderately severe cases may recover under the use of chloral and bromides; (2) that although cases have recovered under tetanus antitoxin alone, its use should not preclude the adoption of measures to meet the urgent symptoms which are almost constantly present, and that in this respect the treatment should resemble that of diphtheria, where the successful issue of a case in which the antitoxin has been used so often depends upon the prompt way in which every symptomatic indication is met; and (3) that the treatment which offers the best prospects of success is that in which tetanus antitoxin is combined with chloral and bromides.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hernia Cerebri.—Non-tuberculous Posterior Basic Meningitis.

A MEETING of this society was held on April 13th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Mr. LAWFORD KNAGGS read a paper on a case of Compound Depressed Fracture of the Skull, followed by Cerebral Abscess and Hernia Cerebri, together with a consideration of the subject of hernia cerebri based on 100 collected cases. The patient, a man, was operated on for compound depressed fracture of the left parietal bone on Sept. 11th, 1894. Though the membranes and the brain were injured, and the wound subsequently suppurated, healing took place in due time, and he became an out-patient on Nov. 28th. He was re-admitted in February with some cerebral symptoms and a protrusion of the soft parts over the bony aperture. On Feb. 4th he was unexpectedly found at the point of death, and the swelling was explored and then opened with a penknife by Mr. Thompson, the resident surgical officer. An ounce of pus was evacuated from a cerebral abscess, and the patient brought round by artificial respiration. Hernia cerebri and paresis of the right arm and leg at once developed. The former grew as large as a hen's egg in a fortnight, remained stationary for three weeks, and then shrank, and by July 7th had disappeared. He left the hospital on Aug. 3rd well, except for some remaining weakness of the forearm muscles and a hesitation in his speech; and a year later his condition remained unaltered, except that he had a fit every eight weeks. He was working as a labourer. In discussing the subject of hernia cerebri the intracranial conditions which produce it were described—viz.: (1) increased tension; (2) a softened or diffluent state of a portion of the cerebral substance; and (3) inflammation of the brain substance, which leads to an increase in bulk, to its softening, and when prolonged to its replacement by granulation tissue, and finally by cicatrix. The inflammation also impairs, suspends, or even destroys the functions of the centres implicated. The duration and size of the hernia are influenced by the extent of the inflammation. The causes are traumatism and sepsis, either separate or in combination. If sepsis be avoided the inflammatory effusion is gradually absorbed and the protrusion will certainly dwindle and disappear after it has reached its maximum. The time required varies from a few days to several months, and depends on the amount of brain involved and the absence or presence of any continued irritation. The results of septic infection are abscess, meningitis, and diffuse inflammation, and abscess is the only one that is not always fatal. Hæmorrhage and abscess may be associated with hernia cerebri, and attention was drawn to the importance of gravity in certain cases and to the sudden but transient enlargement of the tumour, which may result from trivial causes, either local or general, such as probing the wound or an attack of tonsillitis. The prognosis was stated to be good if sepsis were avoided, and it was to be borne in mind that septic infection might be a result, not only of the original injury or consequent operation, but of interference. The results of treatment by pressure, by caustics, and by various operative procedures, as well as of those left to nature, were then fully considered, and the conclusion arrived at that most of the recoveries were due to natural processes, and that most of the successful cases would probably have recovered if left alone. Three more might have recovered

Hosted by Google

nowadays without mutilation of the brain, but for the remaining three excision must have credit given to it. Sepsis was the almost universal cause of death, and the increased percentage of deaths in the operative cases (28·5 per cent.) was not without significance. Treatment should be: 1. Preventive. Every case of compound depressed fracture of the skull should be thoroughly treated, and the wound made aseptic. This is now generally done, and probably accounts for the rarity of the cases in current literature. 2. Non-interference should be the rule, and the tumour allowed to run its own course. 3. Operative treatment may be necessary when abscess is present, and should aim at evacuation, not mutilation. It may be necessary to remove embedded fragments after their position has been demonstrated by skiagraphy, but it was difficult to imagine a condition in which excision could be justified.—Mr. BALLANCE congratulated Mr. Lawford Knaggs on the result of his case and on his exhaustive treatment of the subject. He attributed the rarity of hernia cerebri at the present time to the successful avoidance of sepsis. Provided that there was an aseptic condition, as in surgical operations, extensive injury might be done to the brain without hernia cerebri. After an accident it might be impossible to obtain an aseptic condition of the parts. He found it difficult to believe that the hernia might push through the uninjured dura mater. The cases ought certainly to be carefully treated at the onset, and he was in hopes that the surgeon might be able to deal with and render aseptic compound fractures of the base as well as those of the vault.—Mr. LAWFORD KNAGGS, in reply, said that he thought that he had seen some patients in whom hernia was due to traumatism without sepsis, and in one of the patients who died the post-mortem appearances were quite the reverse of any septic inflammation.

Dr. J. WALTER CARR read a paper on Non-tuberculous Posterior Basic Meningitis in Infants. The object of the paper was to show that there was a distinct form of meningitis, occurring almost exclusively in infants, which has not at present received adequate recognition, though described by Dr. Gee and Dr. Barlow in the St. Bartholomew's Hospital Reports for 1878 under the title of "The Cervical Opisthotonos of Infants"; that it mainly affects the posterior part of the base of the brain, is entirely independent of tuberculous disease, runs a sub-acute or chronic course with fairly characteristic symptoms by which it can be diagnosed during life, and presents very constant and definite post-mortem appearances, although its actual causation remains at present unknown. The description of this disease was based upon eleven cases observed by Dr. Carr at the Victoria Hospital for Children, Chelsea, narrated in detail, and compared with those recorded by Dr. Gee and Dr. Barlow in the above-mentioned paper. All the cases occurred in previously healthy infants under a year old; the onset was gradual in some, sudden in others; but in all, the most constant and characteristic symptoms were severe vomiting, extreme retraction of the head, and stupor passing into coma of remarkably long duration, generally several weeks, the excessive retraction of the head persisting to the last. The cases all terminated fatally, none in less than five weeks, whilst some lived for three months or even longer. At the necropsies (ten in number) inflammation of the pia arachnoid was found over a very definite area at the base of the brain, hydrocephalus in all the cases, and in some closure of the openings between the fourth ventricle and the sub-arachnoid space. In no instance was any sign of tuberculous disease discovered, either in the cranial cavity or elsewhere. The possible causation of the ventricular effusion was fully discussed in the paper. The possible connexions of the disease with injury, ear disease, and congenital syphilis were successively discussed, and reasons given for concluding that none of these could be really causes of the meningitis. It was suggested that possibly there might be some relation between the disease and epidemic cerebro-spinal meningitis, but that bacteriological investigation only could determine this, and at present this had not been carried out. Under diagnosis the chief points of distinction between this disease and other forms of meningitis, especially the tuberculous variety, were fully described. In regard to prognosis, it was stated that, whilst usually fatal, recovery was probably not impossible, and cases were quoted in support of this, and to show that the disease may occasionally give rise to ordinary chronic hydrocephalus. As regards treatment, it was said that medical treatment was probably of little avail, and the question of operative interference, either by tapping the lateral ventricles or by trephining, was therefore discussed. In two of the cases described the former measure was tried without evil effects, and in one with distinct improvement, all acute symptoms subsiding, and the child living for several months. Trephining in two other cases proved rapidly fatal, the great danger consisting in too rapid an escape of fluid.

MEDICAL SOCIETY OF LONDON.

Extroversion of the Bladder.—Spastic Hemiplegia.—Acromegaly.—"Baker's Cyst" of the Knee.—Osteotomy for Deformity.—Sarcoma of the Thumb.—Spontaneous Fractures.—Multiple Tumours of the Skin.

A MEETING of this society was held on April 11th, the President, Mr. REGINALD HARRISON, being in the chair.

The PRESIDENT showed a case of Extroversion of the Bladder treated by left nephrectomy and transplantation of the right ureter through the loin. The patient, now fifteen years of age, came under observation in July, 1895, in a very emaciated condition, with congenital extroversion of the bladder and epispadias. The posterior wall of the bladder protruded, and both ureters were visible. The thighs were excoriated. In January, 1896, the urine having been ascertained to be normal, the left kidney was removed by a lumbar incision, and eleven months later an incision was made in the right loin, and the ureter of the remaining kidney found and divided, and its proximal end brought out to the lumbar incision, where it was attached by one silk suture, and urine at once issued from it. As the ureter was being manipulated there was continuous and violent retching, which was also troublesome for a few hours after the operation. During convalescence there were some unexplained attacks of pyrexia. The urine now flows readily from the wound, where an apparatus is to be worn to collect it. The urine is clear and does not irritate the skin, and there has been no tendency to the deposit of phosphates. The boy is able to maintain the erect position. As there are some signs of cicatrisation in the exposed vesical mucous membrane, any attempts to close it in by plastic operations have been postponed. Possibly this method might enable the surgeon to extirpate the bladder for malignant disease or for some advanced forms of suppurative disease.—Mr. MORGAN inquired what were the reasons for sacrificing the left kidney. The freedom from phosphatic deposit in the urine was very striking. The method was novel, and deserved careful consideration, as ordinary attempts to ameliorate the local condition were usually very disappointing and complete closure rarely obtained. The condition of the bladder did not appear to have been much improved by the operation.—Mr. STANLEY BOYD thought that it was too early to say much about the value of the operation, as there were risks both of ureteral stricture and of "surgical kidney." He could see no reason for removing the left kidney.—The PRESIDENT, in reply, said that he removed one kidney because it would have been extremely difficult to collect the secretion satisfactorily from two orifices.

Dr. ROLLESTON showed a case of Spastic Hemiplegia after Whooping-cough. The patient was a girl, aged thirteen years, with right spastic hemiplegia associated with a varying amount of athetoid movement. The condition dated from an attack of whooping-cough when ten months old, and was considered to be due to hæmorrhage into the cortex from one of the cerebral veins during a paroxysm of coughing. The face, speech, and mental powers were unaffected. The upper limb was extended and hypertrophied. The wrist was flexed and adducted to the ulnar side, and the fingers were flexed into the palm; occasionally, especially on excitement, there was mobile spasm of the fingers. The muscles of the arm and that side of the chest were hypertrophied from the constant spasm. The right leg was spastic; there was no exaggeration of the knee-jerk. The patient was bright mentally, although ill health had interfered with her education.—Dr. MAGUIRE said that without knowing the history the case might have been put down as due to hysteria. He agreed that the only possible lesion was a cortical hæmorrhage. The prognosis was not good, as a large proportion of these cases developed epilepsy about the age of puberty.—Dr. GUTHRIE thought it surprising that cerebral hæmorrhage did not occur more frequently in whooping-cough. He had recently seen a case in which right hemiplegia and aphasia

Hosted by Google

occurred suddenly during an attack of whooping-cough. The hemiplegia passed off after a few months and speech returned, when an attack of left hemiplegia occurred, and the child was now, he feared, permanently dumb.

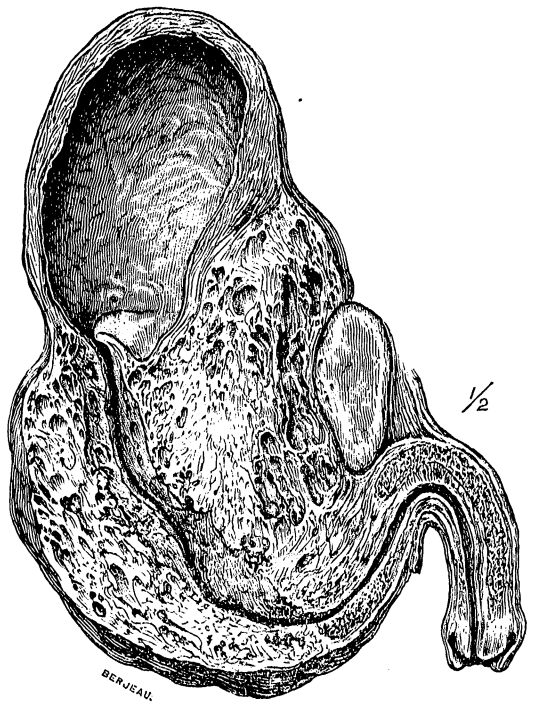
Dr. ROLLESTON also showed a woman, aged twenty-six years, suffering from Acromegaly. For two and a half years the hands and feet had been getting larger, the nose becoming more prominent and the face enlarging, while amenorrhœa had existed for the same period. For a month before admission to St. George's Hospital, in October, 1896, she had suffered from severe headache. Under treatment by thyroid and pituitary extract combined this symptom had been relieved, though the skeletal changes remained. The treatment had been continued with good result since her discharge from the hospital, so that the good result could hardly be explained merely as the result of rest in bed. A somewhat similar beneficial result had been obtained in a more advanced case of the disease. Since pituitary extract alone had been found to be unsuccessful, and since there were some superficial resemblances between acromegaly and myxœdema, it seemed reasonable to try a combination of pituitary and thyroid extracts. Physiologically the action of these two extracts was opposed, and it seemed possible that acromegaly was the result of a disturbance of a chemico-physiological equilibrium maintained in health by the activity of these two glands.

Mr. W. H. BATTLE showed a woman, twenty-four years of age, with a "Baker's cyst" in the calf communicating with the knee-joint. There had been pain and swelling in the calf for some time, and a fluctuating swelling could be felt beneath the deep fascia. On examination it was found that there was a painless effusion, with very little synovial thickening, in each knee-joint, and a semi-membranous bursa communicating with the joint. There also appeared to be a communication between the cyst and the semi-membranous bursa. It was difficult to explain the effusion, which had remained stationary for three years.—Mr. BATTLE also showed a woman, twenty-one years of age, on whom he had performed Osteotomy for Extreme Deformity. There was extreme genu valgum of one leg and equally marked genu valgum of the other. Successive osteotomies by Macewen's method were performed, and the girl, who had previously been bedridden, was now able to walk without pain and without the aid of any apparatus.—Mr. BATTLE also showed a boy who fell and sustained a Compound Comminuted Fracture of the Patella. The wound was cleansed, some of the fragments removed, and others united as far as possible with wire, and the boy had now been able to return to his employment.—Mr. BATTLE also showed a Giant Thumb which he had removed in January from a man fifty years of age, for sarcomatous degeneration of an enchondroma, which had existed, with many others on the hand and forearm, from infancy. The tumour microscopically was a spindle-celled sarcoma, with remains of cartilage tissue. The sudden enlargement appeared to have followed an injury. The man had since died from "chronic bronchitis," possibly associated with secondary growths in the lungs.—Mr. MORGAN said that degeneration of these tumours was very rare. He had recently published a case in THE LANCET in which a congenital tumour degenerated into a sarcomatous growth at the age of fifty years.

Dr. L. G. GUTHRIE showed a Jewish child, two years of age, suffering from Multiple Spontaneous Fractures. The child was brought up on cow's milk and water, the milk being probably of poor quality. Four months previously discoloured patches "like bruises" were noticed about the thighs, arms, and clavicles. On admission to hospital the child was found to be very badly nourished, extremely sensitive to any manipulation, and there were definite fractures of the shafts of the clavicles, femora, and the right humerus, with considerable deformity. Skiagrams were shown demonstrating the lesions of bone. Several of the fractures had united, but there was still mobility of some. He believed the condition was probably due to scurvy-rickets, although there was no positive evidence of the condition, except, perhaps, the bruises. The child had rapidly improved on a diet of milk and cream, with raw meat juice and orange juice.—Mr. MORGAN said that he had just now under his care at the Hospital for Sick Children, Great Ormond-street, a boy seven years of age, also a Jew, with deformities due to a condition similar to that in Dr. Guthrie's patient. He thought the diagnosis of scurvy-rickets questionable, as in that disease the hæmorrhages and fractures were usually near the epiphyses, and not in the centre of the shaft.

Mr. F. C. WALLIS showed a man who had been under treatment for some years for a Mass of Glands on the right side of the neck believed to be lymphadenomatous. There were thirteen of these swellings, some of them as large as a turkey's egg. They were excised and found to be undergoing calcareous degeneration. The wound healed quickly, but lately about 100 subcutaneous tumours had appeared in the adipose tissue of the abdominal wall and elsewhere.

CLINICAL SOCIETY OF LONDON.



Sarcoma of the Prostate.—Ovariotomy in a Child.—Hydatid Cysts of the Liver, Pleura, and Abdominal Cavity.

A MEETING of this society was held on April 9th, the President, Dr. BUZZARD, being in the chair.

Mr. HOWARD MARSH related a case of Sarcoma of the Prostate. The patient, aged fifty-seven years, was admitted into St. Bartholomew's Hospital in May, 1896. Two and a half years previously laparotomy had been performed for a tumour, which on exposure seemed to be a sarcoma growing from the left ilium. As the tumour could not be removed the abdomen was closed. When the patient came into St. Bartholomew's Hospital a tumour was found involving the prostate, and so large that it filled the pelvis, displaced the bladder, and so pressed upon the rectum that the bowels could not act, and the abdomen was becoming distended. Colotomy was performed, but the patient died. On post-mortem examination it was found that, apparently from the dragging action of several pounds of dry fæces in the colon and sigmoid flexure, the bowel at one point had fallen away from the wound and that acute peritonitis had followed. The tumour, which measured 7½ in. by 4½ in., was enclosed in a firm fibrous capsule. On section it was of a whitish colour and firm consistence. On microscopic examination it was a spindle-celled sarcoma. Mr. Marsh remarked that both sarcoma and carcinoma occurred in the prostate, though both were rare. Not a few cases of sarcoma had been met with in quite young children, a good example being that recorded in a boy, aged five years, by Mr. Spanton. The affections had occurred in all the decades of life up to the age of seventy-five years. The chief symptoms were:—1. Difficulty of micturition. In some cases the urethra was completely destroyed by the growth, in other instances, however, micturition had been scarcely, if at all, interfered with. 2. Difficulty of defecation from pressure on the rectum. 3. The presence of a tumour in the situation of the prostate. 4. Hæmorrhage from the urethra; but this was frequently entirely absent. 5. Pain, sometimes only slight, but in some cases extremely severe. 6. The bladder was displaced so that it lay, not in the pelvic cavity, but in the hypogastric region of the abdomen. As to treatment, but little that was satisfactory could be done. Removal of the tumour was usually impossible; in some instances it was necessary to drain the bladder by supra-pubic puncture, while in many colotomy for the relief of intestinal obstruction had been necessary. In cases in which the growth was a firm spindle-celled sarcoma patients had lived for four or five years; but where, as often in children, the tumour was a myxo-sarcoma undergoing softening and tending to infiltrate the surrounding structures, death occurred in the course of a very few months.—Mr. BLAND SUTTON said that knowledge of the minute anatomy of prostate tumours was still very imperfect. The terms "scirrhus" and "encephaloid" were often applied to such tumours from their superficial resemblance to similarly named growths in the mamma. Carcinoma of the prostate was most liable to occur in advanced life, and gave rise to secondary deposits in the bones. The soft tumours in young people, often described as "encephaloid," were probably sarcomata, as in the case related by Mr. Marsh. Sarcoma might occur in children under the age of ten years. He mentioned the case of a boy, seven years of age, who, after difficulty in emptying his bladder, extending over a few weeks, came under observation with a soft tumour presenting in the perineum. An exploratory incision was made, and a piece of the growth removed and examined and found to be sarcomatous. He died soon afterwards, and secondary growths were found in the lungs. The condition

Hosted by Google

of the parts after death is shown in the accompanying illustration. He had also received from others sections of similar tumours removed from children. The prostate therefore resembled the retina, ovary, and kidney in the liability to sarcoma in the first ten years of life, the liability recurring in the third decade.—Mr. JOSEPH GRIFFITHS showed a specimen of sarcoma of the prostate in a child extending along the urethra. He insisted on the importance, for purposes of diagnosis, of examining the condition of the urethra through the rectum. A bougie should be first passed down the urethra. In simple enlargement of

Sarcoma of the prostate, from a boy aged seven years.

the prostate there was never infiltration behind the membranous part of the urethra, but in malignant disease of the prostate thickening of the urethra in this situation could almost always be felt.—Mr. J. H. TARGETT showed a specimen of the same kind from the museum of Guy's Hospital. He thought that many of these cases arose in the connective tissue of the recto-vesical folds.—Mr. S. G. SHATTOCK remarked on the atrophy of the glandular elements of the prostate after double castration. It was possible that this was partly due to loss of internal secretion of the testis, and seeing the effect that double ovariotomy appeared to have in arresting malignant growths of the mamma he suggested a trial of double castration in these cases.—Mr. BUCKSTON BROWNE did not think that infiltration was always to be felt behind the urethra, and mentioned a case in which it was almost all in front, giving rise to a distinct prominence above the pubes. He remarked that hæmorrhage was more common in carcinoma of the urethra than in sarcoma. Severe neuralgic pain, often simulating double sciatica, was frequently met with in carcinoma of the prostate.

Mr. RAYMOND JOHNSON reported a case in which Axial Rotation of the Pedicle of an Ovarian Cyst was met with in a child five years of age. She had been ailing for six months, and during that time had suffered from numerous attacks of abdominal pain attended with diarrhœa and vomiting. These attacks increased in frequency and severity, and three weeks before the child was brought to the Victoria Hospital for Children the abdomen was noticed to be swollen. On admission the child was thin and looked ill; the temperature was 101° F. The abdomen was considerably distended, and the right half was occupied by a tender elastic swelling, which was most prominent below and to the right of the umbilicus. The diagnosis of localised tuberculous abscess of the peritoneum was made, and operation was at once undertaken. An incision was made over the prominent part of the swelling in the right linea semilunaris and a cyst of the right ovary was exposed. The wall of the cyst was hæmorrhagic and the pedicle had undergone two complete rotations. Ovariotomy was performed, the child making an uneventful recovery. The general features of the case were so suggestive of tuberculous peritonitis that the question of the diagnosis between a localised abscess and a cyst was not really taken into consideration. The case was recorded on account of its rarity, no other record of axial rotation of an ovarian pedicle in a young child having been discovered. Indeed, ovariotomy in a child of five years is sufficiently unusual to make the case of interest.—Mr. BLAND SUTTON said that out of all the cases of ovarian tumour that he had collected, only 15 per cent. were in children under ten years of age. Statistically, ovariotomy appeared to be most successful between the ages of ten and fifteen years; below the age of ten years it was not so successful. Twisting of the pedicle was unduly common in children, although the usual causes of that condition in adults—association with uterine myoma, pregnancy, or tumour of the opposite ovary—were not present.

Mr. W. G. SPENCER related a case in which Hydatid Cysts were removed from the Left Pleural Sac, from behind the Mesentery, and from the Right Lobe of the Liver. The case was that of a young women, aged twenty years, whom he had seen with Mr. Thomas Bond. She was supposed to have suffered from an attack of pleurisy, and they thought that an empyema had formed and was tending to point below the left costal margin. On incision of the prominent swelling a hydatid cyst was found occupying the lower half of the left pleural cavity. The parasitic cyst was removed without tearing it by passing a stream of water from an irrigator between it and the adventitious cyst. Upon the patient coughing the lung expanded, burst through the adhesions representing the adventitious cyst, and filled the whole cavity. The patient recovered the complete use of the left side of the chest. Meanwhile, dulness and resistance increased on the right side in the region of the liver from the nipple down to the level of the umbilicus. Two months after the first operation an abdominal incision was made, the liver hooked up, the large and small intestines pushed aside, the mesentery cut through, and the cyst, situated behind the mesentery and distinct from the liver, reached. The parasitic cyst was removed as before and the adventitious cyst washed out and sewn up. Finding that the cyst in the right lobe of the liver could not be reached, the abdominal wound was sewn up. An incision was then made into the pleura through the tenth interspace in the right mid-axillary line, the diaphragm stitched to the upper edge of the wound, and then incised. The cyst was reached one and a half inches within the liver and was drained. Fluid, shreds, and hooklets came away through the wound, and the patient has gradually recovered complete health. Mr. Spencer pointed out the dangers which might have attended operation either from sudden flooding of the lungs or from hæmorrhage, and how much safer and better than aspiration were incision and removal of the cyst.—Mr. HOWARD MARSH congratulated Mr. Spencer on the result of his treatment of the case. He thought that everyone would endorse his condemnation of the old practice of aspirating hydatid cysts. He had found the method of floating the cyst by irrigation described by Mr. Spencer very easy and successful. The closure of the adventitious cyst was often a very long and tedious process.—Mr. F. C. WALLIS had seen two patients suffering from hydatid cyst die directly after tapping. If the cyst was dead there were usually adhesions between the parasitic cyst and the adventitious cyst, and the method of washing out might fail. In that case it was quite easy to separate the parasitic cyst with the finger.—Mr. MAKINS said that cases like this one gave the surgeon great anxiety, as when it was discovered that there were more than one cyst he was left in doubt as to how many more might be distributed among the internal organs. The closure of the fistula was often a difficult result to secure; he recalled one case in which such a fistula from a hydatid cyst of the spleen never closed, the patient ultimately dying from amyloid disease. In some cases these sinuses had been shown to become tuberculous. Among the many objections to aspiration was the chance that the cyst might be packed with daughter cysts and only a few drops of fluid obtained when there was really a large cyst present.

OBSTETRICAL SOCIETY OF LONDON.

The Treatment of Placenta Prævia by Champetier de Ribes' Bag.—Exhibition of Specimens.

A MEETING of this society was held on April 7th, Dr. C. J. CULLINGWORTH, the President, being in the chair.

A vote of condolence with the family of the late Sir Spencer Wells was passed.

Dr. G. F. BLACKER read a paper on the Treatment of Placenta Prævia by Champetier de Ribes' Bag. He said that in the more severe cases of hæmorrhage from placenta prævia Champetier de Ribes' bag might be employed in place of version by introducing it into the amniotic cavity after rupture of the membranes. Used in this way the bag acted both as a tampon in arresting the hæmorrhage by pressing the separated portion of the placenta firmly against the uterine wall, and also as a dilator of the cervical canal and a very powerful stimulus to uterine contractions. The use of the bag was therefore advocated in grave cases of hæmorrhage from placenta prævia as an easy method of arresting the hæmorrhage, and at the same time as likely to reduce the heavy fœtal mortality which usually occurred in these cases after the performance of version. Dr. Blacker had treated 5 cases of placenta prævia in this way, and had collected 17 other cases similarly treated. The details of these cases were given in full in the tables accompanying the paper. An analysis of the chief features of interest in the cases was given, showing that only in one case did severe hæmorrhage occur after the introduction of the bag; that such hæmorrhage might, as a rule, be readily controlled by traction upon the bag; that in none of the cases was any difficulty experienced in introducing the bag or was preliminary dilatation of the cervix necessary; and that the average length of time required for the complete dilatation of the cervix after the introduction of the bag was five hours and ten minutes. Of the mothers, 1 died from septicæmia—probably present on her admission to the hospital—before the introduction of the bag. Of the others, 5 had a slight elevation of temperature during the puerperium, the highest point reached being 100·6° F.; while in the remainder recovery was perfect and the puerperium afebrile. Of the 22 children, 14 were born alive, and 8, or 36·3 per cent., dead. Of the 14, 4 subsequently died, giving a total mortality of 54·5 per cent. The advantages claimed for the bag were: (1) ease and facility of introduction; (2) the certain arrest of the hæmorrhage; (3) any further hæmorrhage was controllable by traction upon the bag; (4) the bag, and not the child's body, dilated the cervical canal; (5) the ease of delivery after expulsion of the bag; (6) the fact that the bag was a very powerful stimulus to uterine action; and (7) the lessened fœtal mortality as compared with the results obtained after version. The objections brought against the use of the bag were considered—viz., the risk of septic infection, the danger of rupture of the uterus, and the displacement of the presenting part caused by its introduction. The further objections that the bag was difficult to introduce, and that preliminary dilatation of the cervix was required, were shown to be groundless. Even in cases of central placenta prævia the use of the bag was practicable and likely to give results just as good as, if not better than, the performance of version.—Dr. HERMAN agreed with Dr. Blacker's practical and useful paper. He thought the bag was a better plug than the half breech, because it pressed on the whole circumference of the lower uterine segment, while the half breech did not. The hæmorrhage in placenta prævia was produced by dilatation of the cervix, hence the bag could always be introduced when considerable hæmorrhage had occurred. His own experience of the use of Champetier de Ribes' bag in placenta prævia was altogether favourable.—Dr. HORROCKS said that he had for some years used Champetier de Ribes' bag, not only in cases of placenta prævia, but also in all cases where formerly Barnes's hydrostatic dilators had been used. In cases of placenta prævia the bag had been placed in the amniotic cavity only when the membranes had been ruptured. In cases where they had been intact care had been taken to avoid rupture. The presenting portion of the placenta had been detached by sweeping the finger round the lower zone, and then the bag had been passed into the uterus so as to lie below the membranes. Good results had been obtained by this method, which had much to be said in its favour. In so-called accidental hæmorrhage the membranes were ruptured because it was the quickest method known of securing uterine contraction, which stopped the hæmorrhage, whereas in the hæmorrhage from placenta prævia the principle of treatment was precisely the reverse—that is, instead of invoking uterine action it was endeavoured to avoid it and to dilate and deliver by artificial means, and only when the cervix was sufficiently dilated were the membranes ruptured. He considered that the chief danger was sepsis from the bag itself, which was difficult to get aseptic owing to its composition of indiarubber and the material used to render it waterproof.—Dr. H. R. SPENCER said he had had considerable experience of placenta prævia and of the employment of Champetier de Ribes' bag, though he had not employed the bag in the treatment of placenta prævia, but usually for the induction of premature labour. That experience led him to agree with most of Dr. Blacker's conclusions, but he thought that some further points should be taken into account in order that discredit might not be brought upon this method of treatment by its adoption in unsuitable cases. In cases of complete placenta prævia he doubted whether it was advisable to use the bag unless an edge of the placenta could be separated; for the child in these cases almost always died, and it would generally be impossible so to control the bag during its introduction as to be sure that it did not push up the placenta instead of passing into the amnion, and that the hæmorrhage which it was intended to check was not increased by the treatment. Dr. Spencer called attention to the paper of Dr. Camille Juge, which had appeared since Dr. Blacker's paper was written, in which an account was given of 9 cases treated by the introduction of the bag into the amniotic cavity. Of these 9 cases, 3 mothers died and 6 children were born dead. These cases, added to those in the table, gave a maternal mortality of 13 per cent. and a fœtal mortality of at least 58 per cent. The bag often caused a great deal of pain, and in three of Dr. Juge's cases it produced syncope—a very grave condition in cases of this nature. It also often took a long time to induce labour, as long as twenty hours in 2 of the cases in the table, whereas he (Dr. Spencer) found that after version the labour was over in 16 out of 17 cases in three hours, and in the seventeenth case within five hours.—Dr. BLACKER, in reply, said that he was indebted to Dr. Herman, not only for the remarks he had made about his paper, but also for the fact that it was mainly on his recommendation that he had first employed this mode of treatment in placenta prævia. He thought introduction of the bag after rupture of the membranes was certainly superior to its introduction before, as the latter method was almost certain to be accompanied by an unnecessary and avoidable amount of hæmorrhage.

The following specimens were exhibited:—

Mr. TARGETT: Large Encysted Peritoneal Abscess simulating Ovarian Cyst.

Dr. DRUMMOND ROBINSON: Cystic Ovaries removed by Anterior Colpotomy.

Dr. LEWERS: (1) A Monster, apparently consisting of a somewhat spherical mass of flesh with one limb attached; (2) a Skiagraph of the Monster; and (3) a Uterus with Fibroids removed by Abdominal Hysterectomy.

Dr. EDEN: Incomplete Decidual Cast of the Uterus from a case in which there was no evidence of Extra-uterine Gestation.

Dr. BOTTOMLEY: (1) A Fœtal Monstrosity; and (2) a case of Fœtus Compressus.

Dr. DUNCAN: Further Specimens of Fibroid Tumours of the Uterus removed by the Intra-abdominal Method.

Dr. HERMAN: Specimen of Ectopic Pregnancy going nearly to Term in the Peritoneal Cavity, the placenta being attached to the top of the uterus.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Microscopical Aspects of Certain Lesions induced by Dental Caries.

AN ordinary meeting of this society was held on April 5th, Mr. JOHN FAIRBANK being in the chair.

Mr. FAIRBANK referred to the death of Mr. Salter, and remarked that the council had sent a letter of condolence to the family in the name of the society.

Mr. HOPEWELL SMITH read a paper on the Microscopical

Hosted by Google

Aspects of Certain Lesions induced by Dental Caries. His paper dealt chiefly with the various calcareous formations met with in the pulp and on the walls of its cavity. He remarked that the formation of such masses was due not only to caries, but also to traumatism, senile changes, and obscure conditions, and suggested the following classification:—1. Calcareous degeneration of the pulp through changes in the pulp alone: (*a*) common, due to vascular changes in the pulp in association with caries; and (*b*) rare, due to idiopathic or constitutional changes—e.g., gout. 2. Secondary dentine in pulp cavity, through changes in the primary dentine and pulp: physiological, due to senile conditions of both permanent and long-retained deciduous teeth. 3. Adventitious dentine in the pulp cavity, through changes in the primary dentine and pulp, the result of caries. Mr. Hopewell Smith then referred to the fact that carious stimulation of the dentine was associated with marked cellular activity on the part of the pulp, and he discussed the question under three headings—namely, conditions associated with (*a*) superficial caries; (*b*) deep caries; and (*c*) penetrating caries. The conclusions arrived at were—(1) that nearly every degree of dentinal change is attended with hyperæmia and cell proliferation in the pulp tissues and, generally speaking, the formation of adventitious dentine; (2) that the latter may have its origin as a conversion or secretion of the dento-genetic cells, producing, on the one hand, the areolar, laminar, or hyaline varieties, when the formative cells alone happen to be concerned, and, on the other hand, the fibrillar or cellular forms when odontoblasts or connective tissue cells are by chance incorporated in the deposit; (3) that there are no proofs that the cells called odontoblasts take any part in the production of the matrix of the new dentines, the term being therefore a misnomer; and (4) that the new dentines by a system of extension from the affected areas may be just as much subjected to the peptonising action of the micro-organisms as the primary dentine of the tooth.—Mr. MUMMERY, Mr. STORER BENNETT, Mr. F. J. BENNETT, Mr. GOADBY, and Dr. PARE took part in the discussion, and Mr. HOPEWELL SMITH briefly replied.

LIVERPOOL MEDICAL INSTITUTION.

Intermittent Hemiplegia.—Tetanus.—Enucleation of Uterine Fibroids.—Operative Treatment of Injured and Painful Blind Eyes.

A MEETING of this society was held on April 8th, Mr. ROBERT JONES, Vice-President, being in the chair.

Dr. ALEXANDER DAVIDSON read notes of a case of a man, aged seventy-three years, who had Intermittent Attacks of Hemiplegia. The patient was taken into hospital on Jan. 18th at 6.30 P.M. suffering from left hemiplegia; two hours later he recovered power in the face and limbs. On the morning of Jan. 19th there was no paralysis in the arm or leg; at 12 mid-day paralysis returned; at 1.45 P.M. power was gradually recovered. On Jan. 20th paralysis returned and was permanent.—Dr. KENNAN referred to a case of a man with Complete Left Hemiplegia, which disappeared in a quarter of an hour, only to return half an hour later and become permanent.

Dr. CARTER related two cases of Tetanus in which he had used the tetanus antitoxin. The first case was that of a boy, aged fourteen years, in whom the symptoms of tetanus were well marked; he had a slight wound on the back of the hand. Antitoxin from the Institute of Preventive Medicine was injected on three occasions, the amount used being 10 c.c., and during this time no other medicine was used. As the patient became worse, having almost constant spasms, opisthotonos, and no sleep, chloral and gelsemium were given with marked relief to the symptoms, and the patient ultimately recovered. The second case was that of a man, aged twenty-six years, who was kicked by a horse on the finger and had marked symptoms of tetanus. An injection of 30 c.c. of antitoxin obtained from Paris was given and a mixture of chloral and gelsemium was also taken. The symptoms becoming worse, 24 c.c. of antitoxin were injected, but the spasms became continuous and the man died. Dr. Carter did not think that the antitoxin had produced any material effect in these cases.

Dr. ALEXANDER described a method of Transperitoneal Enucleation of Uterine Fibroids, which he advocated as a substitute in many cases for removal of the appendages and for partial hysterectomy or pan-hysterectomy. Its advantages were greater safety without any mutilation of the patient. The operation consists of a median laparotomy, a longitudinal incision in the uterus in the median line down to the fibroids, their enucleation through one opening, closure of the incision in the uterine wall by catgut sutures, packing of the cavity occupied by the fibroid for forty-eight hours with iodoform gauze, an end of the gauze being left out of the lower end of the abdominal wound, and temporary ventro-fixation of the uterus whilst the cavity is drained. He related six cases, all successful, the number of fibroids removed varying from one to twenty-six.—Professor WALLACE remarked that the operation was not of wide application or fitted for single tumours.—Mr. HAWKINS-AMBLER said that Dr. Alexander's operation appeared to be a good one.

Mr. BICKERTON read a paper on the Operative Treatment, Past and Present, of Injured and Painful Blind Eyes, giving an Historical Sketch of the old practice of Extirpation of the Globe. He alluded to the alternative methods of treatment—e.g., optic neurotomy and neurectomy—as procedures to be discarded, and strongly advocated the performance of Mules's operation in all suitable cases.—Mr. G. E. WALKER doubted if it was worth incurring the great suffering caused by the introduction of a foreign body into the eye in order to bring about a little improvement in the appearance and mobility of an artificial eye.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Surgical Treatment of Gall-stones.

A MEETING of this society was held on March 25th, the President, Mr. RECKLESS, being in the chair.

Mr. PYE-SMITH showed a case of Supposed Fracture-dislocation of the Cervical Spine between the third and fourth vertebræ without Paralysis. The patient, a man, aged twenty-six years, fell six feet, alighting on the top of the right side of the head, nine months ago. The head was in a flexed position and could not be fully extended. There was pain in the region supplied by the supra-clavicular nerves.

Mr. HERBERT HALLAM showed a boy with Mediastinal Growth.

Mr. CONNELL showed a specimen of Tumour growing through the Orbit and extending widely into the Cranial Cavity.

Dr. SORLEY read notes of a case of Abscess of the Liver.

Dr. SINCLAIR WHITE read a paper on the Surgical Treatment of Gall-stones, and presented a tabular statement of the cases—nine in number—he had operated on. Operations on the gall-bladder were best classified under two heads: (*a*) those of necessity, and (*b*) those of expediency. Among the former the most frequent causes were acute suppuration of the gall-bladder, complete obstruction of the common bile-duct from an impacted calculus, with permanent jaundice and suppurative cholangitis. Among the latter chronic distension of the gall-bladder and repeated severe attacks of biliary colic occurred. Cases of chronic distension were common, and should not be dealt with surgically unless the condition gave rise to discomfort or interfered with the health of the patient. When repeated and severe attacks of biliary colic were present an important point, and one that was commonly lost sight of, was whether gall-stones appeared in the fæces. Should these be found after each attack it was right to wait, in the reasonable hope that eventually a natural cure would result; on the other hand, their absence was an indication for cholecystotomy. The success attending the employment of Paul's tubes in intestinal surgery had induced Dr. White to extend their application to the gall-bladder. A glass tube three inches in length and a third of an inch in diameter, with a constriction at each end, was employed. One end was tied in the gall-bladder and the other connected by means of a rubber tube with a bottle for collecting bile. The parietal peritoneum was stitched around and to the peritoneal covering of the gall-bladder on the proximal side of the ligature. By this means the possibility of fouling the peritoneum was avoided. The first dressing was not disturbed for ten days, by which time the ligature had cut its way through the gall-bladder and the tube could be removed.

Hosted by Google

The device had not only abolished the necessity for frequent change of the dressings, but materially shortened the time required for the operation. In one case, that of a woman weighing sixteen stone, the abdominal fat was four inches thick, and it was impossible to bring the gall-bladder to the surface. The case was successfully dealt with by introducing a teacup into the abdomen and allowing the contents of the gall-bladder to fall into it. In another case, where there had been innumerable attacks of severe colic followed by jaundice, the gall-bladder was filled with biliary sand. It was out of the question to suppose that this could have produced blocking of the common duct, and the case goes to prove, observations to the contrary notwithstanding, that transient jaundice may be produced by catarrhal inflammation spreading from the gall-bladder to the common duct.—The PRESIDENT, Mr. LOCKWOOD, Mr. PYE-SMITH, Mr. CUFF, Mr. SNELL, Mr. CHEESEWRIGHT, Dr. RHODES, and Dr. ADDISON made remarks.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Infective Endocarditis.—Roentgen Photographs.—Locomotor Ataxy.

A MEETING of this section was held on March 26th, Sir CHRISTOPHER NIXON being in the chair.

Dr. M. A. BOYD described a case of Infective Endocarditis. The patient was a man, aged twenty-five years, who died, after an illness of three days' duration, marked by pyrexia, delirium, and petechial eruption. At the necropsy there were found miliary abscesses in the kidney and myocardium, and the mitral valve presented an area near the margin of one cusp devoid of endocardium and coated with recent fibrin. The blood was fluid. Sections made from the mitral valve showed extensive necrosis and the margin fringed with compact clusters of cocci. The capillaries of the myocardium were plugged with cocci and the kidney showed similar conditions. Cultures produced pyococcus aureus. The illness dated from severe exposure to wet and cold. The mode of entrance of the organisms was otherwise unexplained. There had been no disease of the middle ear and there was no indication at all in any organ of a primary seat of disease.—Dr. E. J. M'WEENEY said that on cultivation the staphylococcus aureus was obtained, and a plate cultivation showed the liquefying power of the organism upon gelatin. The organisms produced a pale yellow colour, and had evidently been circulating in the blood of the patient.

Dr. LANE JOYNT gave a lantern exhibition of a series of thirty-five X Ray Photographs illustrative of various pathological conditions and showing the extent and utility of this aid to medicine and surgery. Four cases of Colles' fracture were shown, of which three cases had fracture of the styloid process of the ulna. The bones of tuberculous patients when rendered visible by the x rays showed some difference from sound bone. The most noticeable feature was the homogeneous appearance of the ends of bones, such as the phalanges, with marked atrophy of the compact covering, and in some cases the shafts of the bones were seen to be in a similar condition. The bones as a whole were more transparent than sound bone, even in parts not showing the clinical signs of disease.

Dr. COLEMAN and Professor O'SULLIVAN described a case of Locomotor Ataxy. The patient was a man, aged forty-one years. He had never had syphilis, but had suffered much from exposure to wet and cold. His symptoms began two and a half years before his death with lightning pains in the legs, followed six months later by slowness in micturition and occasional incontinence of urine. Eighteen months before his death he had transient diplopia, stumbled in the dark, and felt unsteady on his legs; about the same time he noticed numbness of the fingers of his left hand. The unsteadiness in walking progressed for the next twelve months, at the end of which time he suffered from painful tenesmus and girdle sensation. On admission to hospital his symptoms were as follows: slightly ataxic gait; incoördination of movements of the arms; Romberg's sign well marked; tactile sensation deficient over the distribution of the left ulnar nerve, less so in the right hand; thermo-anæsthesia in the left arm and both legs, with slight analgesia and retarded transmission of painful sensations; Argyll-Robertson pupil; loss of knee-jerks and of plantar, cremasteric, and abdominal reflexes. The nutrition of the toe-nails and of the skin of the soles of the feet was much impaired. He had old-standing tuberculo-fibroid disease of both lungs, and he died five weeks after admission to hospital from disseminated pulmonary tuberculosis.—Professor O'SULLIVAN said that the post-mortem examination showed thickening and sclerosis of the aortic valves, cavities, fibroid changes, and bronchiectasis in the right lung and disseminated tubercles in the left. On microscopic examination the nerves of the cauda equina showed increase of endoneurium and marked thickening of the inner coats of the arteries. The cord showed degeneration of the posterior columns, which could be traced from the lower coccygeal region, where the cord was two millimetres in diameter, to the medulla oblongata. The ventral field of the posterior columns was free from degeneration throughout. A narrow zone running along the median septum was free in the lower part of the cord. In the dorsal region the medullated fibres of Clark's column had entirely disappeared. The posterior roots outside the cord were markedly degenerated up to about the fifth dorsal segment; from this on to the second dorsal segment they were almost free, and the path of these undegenerated fibres in the cord formed a narrow strip, which could be traced along the outer margin of Goll's column to the medulla, where they ended in the nucleus cuneatus. Above the second dorsal segment the degeneration of the posterior roots recurred, and was most marked in the cervical enlargement. Their path in the cord was marked by a strip of degeneration lying outside the last mentioned and also passing to the nucleus cuneatus. Above the cervical enlargement the degeneration of the incoming roots suddenly ceased. The degeneration was most marked throughout on the left side. Two of the spinal ganglia which were examined showed slight proliferation of the layer of cells lining the spaces occupied by the ganglion cells.

Reviews and Notices of Books.

Ospa i Ospoprivivanié: Pamiati Jenner'a. (*Small-pox and Vaccination: To the Memory of Jenner.*) Vol. I. By Dr. V. O. HUBERT. St. Petersburg: The Russian National Health Society. 1896. Price 3 roubles.

FOR this handsome volume we have nothing but praise. Last year, it will be remembered, the Russian National Health Society organised an elaborate commemoration of the centenary of Jenner's great work in proving the value of vaccination as a preventive of small-pox. For various unforeseen reasons the commemoration was postponed, and was finally held just before the close of the year. A description of the memorial meeting and of the exhibition connected with it appeared in our columns at the time. The volume now under notice was prepared by the secretary of the society and issued on the day of the meeting. The second volume is in course of preparation. The work could scarcely have been put into more capable hands than those of Dr. Hubert. The present volume contrives in the course of some 530 pages to give a complete history of small-pox and the methods of dealing with it from the very earliest historical times down to the beginning of the present century. In the earliest chapters we find a good account of small-pox, or of such scanty historical references to it as remain, in ancient Egypt, in China, in India, among the Hebrews, and later among the Arabians; and here is included a complete Russian translation, the first ever published, of Rhazes's well-known essay "De Variolis et Morbillis." A history of small-pox in the middle ages, followed by a full account of the practice of small-pox inoculation, leads naturally to the epoch-making work of our truly great fellow countryman, who robbed small-pox finally and for ever of the terrors it possessed for our ancestors. The story of Jenner's experiments and the final triumph of his discovery is, or should be, well known to most educated people in all countries, but it bears the

Hosted by Google

re-telling, especially when such a wealth of detail and lavishness of illustration are added as in the case of the present Russian version. And here we must add a word of special praise for the illustrations throughout the volume. There are in all between 400 and 500 portraits, drawings, facsimiles of ancient manuscripts, title pages, and so forth, and they are most of them excellently reproduced. We say "most" advisedly, for it is a matter of regret that some of the portraits are not so pleasing as they might be. Dr. Hubert has succeeded in collecting between thirty and forty different portraits of Jenner[1] and large numbers of likenesses of other celebrities and authorities upon small-pox, but in transferring by one of the mechanical processes the lines of old prints to new, very highly glazed paper the result is not in all cases satisfactory. These are, however, small blemishes, and the remainder of the illustrations, some of which are in colours, are excellent. The reproductions of Jenner's drawings for his "Inquiry" are particularly good; they are almost indistinguishable from the originals. Not only the "Inquiry," but all the other productions of Jenner's pen, including his verses, are here printed in full, either in Russian translation or in the original English, or in both, and a full life of Jenner completes the chapters relating to the introduction of vaccination.

The chapters on Small-pox and on Inoculation and Vaccination in Russia are naturally among the fullest in the book, and contain a vast amount of curious and interesting information. We have only space to call attention to the curious popular pictures here reproduced. These were apparently issued by the Government or philanthropic societies early in the century and distributed among the peasants. They are mostly crude, but very unmistakeable, representations of the disastrous effects of small-pox and the beneficial effects of vaccination, and it must have been the dullest of intellects that failed to read the lesson they were meant to teach.

It is a matter of regret that this work is in a language so little known outside its own country as Russian. But in view of the great number of illustrations it contains, and of the fact that it is dedicated to the memory of Jenner and his work, there is no reason why it should not find a welcome place in the libraries of many English medical men.

A Handbook of the Diseases of the Eye and their Treatment. By HENRY R. SWANZY, A.M., M.B. Dub., F.R.C.S. Irel., Surgeon to the National Eye and Ear Infirmary. Sixth Edition. London: H. K. Lewis. Pp. 608, post 8vo. Price 12*s.* 6*d.*

WE are glad to welcome another edition of this excellent manual. The changes that are to be found in the present edition, considering that only two years have elapsed since the appearance of the last, are of course not extensive, and many pages are simply a reprint; but the author has devoted much attention to the ocular diseases that are associated with morbid conditions of the brain and has greatly improved and extended the arrangement given in previous editions. The following is the order in which he has described these affections: Ocular diseases and symptoms liable to accompany focal disease of the brain, which include, amongst others, hemianopsia, alexia, visual aphasia, dyslexia, amnestic colour-blindness and mind-blindness; ocular diseases and symptoms liable to accompany diffuse organic diseases of the brain, as sclerosis, meningitis, epilepsy, and chorea; ocular diseases and symptoms liable to accompany diseases and injuries of the spinal cord, as tabes dorsalis, myelitis, syringomyelia, myotoma congenitalis, and acute ascending paralysis; nervous amblyopia or asthenopia; and, lastly, various forms of amblyopia—such as scintillating scotoma, congenital and reflex amblyopia, and erythropsia. Mr. Swanzy's work contains in an appendix a very useful enumeration of the regulations in respect to vision which disqualify candidates for admission into the public services, and it is much to be desired that these rules should be placed before those who are interested in the education of the young before they have commenced their special studies.

LIBRARY TABLE.

On the Plans of Modern Asylums for the Insane Poor. By JOHN SIBBALD, M.D. Edin., Commissioner in Lunacy for Scotland. Edinburgh: James Turner and Co. 1897.—In view of the expressed intention of the English Lunacy Commissioners to furnish reduced plans of proposed asylums, embodying the latest approved architectural arrangements, this paper, written by Dr. Sibbald for the information of the authorities of the recently constituted Edinburgh Lunacy District and since reprinted, appears very opportunely. The authorities on whom devolves the duty of making provision for the steadily increasing numbers of the registered insane will now have ample opportunity of studying the matured opinions of the heads of the central departments on the subject of modern asylum requirements. Dr. Sibbald has acted wisely in publishing his views; they breathe the spirit of progressive enlightenment which characterises, and has characterised, the administration of Scottish lunacy affairs. The author describes the gradual development which has taken place during the century in the care and treatment of the insane and in their environment. He gives a description of several asylums built at different periods and shows the progressive steps that have been made with regard to the housing of the insane poor. As illustrating the latest type of asylum in the British Isles he describes the Gartloch Asylum (City of Glasgow), which is built on the pavilion system; and he instances the Middlesex Asylum at Claybury and the West Riding Asylum at Menston as being, from certain points of view, among the most admirable of the newer asylums. The village system which has recently come into favour in Germany and the United States meets with his warmest approval, and he gives a lucid and interesting account of the Alt-Scherbitz Asylum near Halle in Prussia. This asylum is administered on the village system, and Dr. Sibbald regards it as the type of asylum that conforms in the highest manner to the most modern and the best idea of what an asylum ought to be. He states that it carries further than any other type the idea of making asylum arrangements similar to those of ordinary life, and every development in asylum construction which has stood the test of experience has been made in this direction. Altogether this is an instructive and readable paper, and should certainly accomplish the object for which it was written.

Transactions of the American Gynæcological Society. Vol. XXI., for the year 1896. Philadelphia: William J. Dornan.—The volume before us contains several interesting contributions. Among these may be particularly mentioned a paper on the Liability to Prosecution for Damages in Abdominal Surgery by Dr. Kirkley, and one by Dr. John Byrne on the Relative Merits of Total or Partial Hysterectomy for Cancer of the Cervix by Ordinary Methods and Supra-vaginal Excision by Galvano-cautery. Dr. Boldt contributes a paper on the Implantation of the Ureter into the Bladder by Abdominal Section for the Cure of Uretero-Vaginal Fistula. There is also a paper by Dr. Charles Noble on Suspensio-uteri, with Reference to its Influence on Pregnancy and Labour. The question of the best technique to be adopted in abdominal hysterectomy for fibroids is once more to the front in a valuable paper by Dr. Byford, entitled "Drainage of the Stump and Connective Tissue in Abdominal Hysterectomy

[1] One portrait (that on p. 351, a seated figure in cocked-hat) is surely an error. It is, we believe, not a portrait of Dr. Jenner, but of Dr. James Sims, M.D., LL.D.

Hosted by Google

for Fibroids and Inflammatory Disease." The volume quite maintains the high standard of excellence reached by its predecessors.

Dental Materia Medica, Pharmacology, and Therapeutics. By CHARLES W. GLASSINGTON. London: J. & A. Churchill. 1896. Price 6s.—A good text-book dealing with dental materia medica has been sorely needed for some time, and although we can hardly state that Mr. Glassington's book comes up to our most sanguine expectations, nevertheless it must be regarded as a distinct advance on anything as yet published. There are some omissions and a few inaccuracies which will no doubt be remedied in a future edition and so increase the value of the book, which should be a welcome help to the dental student and practitioner.

JOURNALS AND REVIEWS.

Science Progress (April, 1897). — This issue provides abundant material for study and reflection and should suit a very wide range of readers. Perhaps the most widely interesting contribution is that by Professor Poulton (Oxford) on a Remarkable Anticipation of Modern Views on Evolution, in which the author draws attention to the very pregnant conclusions of "that great pioneer of modern anthropological and ethnological research James Cowles Pritchard" (born 1786) as bearing upon the views of the present day in regard to the transmission of acquired characters. These views, which were arrived at independently by Professor Weismann over half a century later, appear, strange to relate, to have passed unnoticed. Even Darwin must have overlooked all notice of the remarkable anticipations published in a second edition of Pritchard's work on "Researches into the Physical History of Mankind." The issue contains also some papers of interest to the physicist, chemist, botanist, and student of medicine, while a paper on "Wind Scorpions" contains a very interesting account of these curious but somewhat discomposing creatures. They occur in Arabia, and are described as looking like "a piece of thistledown driven before the wind," and possess somewhat remarkable anatomical characters. They have terrible jaws and exhibit in general very formidable powers.

Journal of Mental Science (April, 1897).—In the current number of this quarterly Dr. Julius Mickle continues his interesting observations on Atypical and Unusual Brain-forms in Relation to Mental States. Dr. J. F. Woods relates his personal experience of suggestion, with or without hypnosis, as a therapeutic agent in the treatment of mental and nervous diseases. He commenced experiments in 1892 with very decided scepticism as to the value of this method; but the results he has achieved in the course of five years have convinced him of its efficacy, and he affirms that, in certain disorders, no other mode of treatment can compare with it. Dr. C. Hubert Bond, in a paper of much clinical interest, throws considerable light upon the relationship of diabetes, including glycosuria, to insanity. In a vigorous article Dr. Mercier discusses the question of Medical Reticence, both as regards sane and insane patients. He formulates his views in no half-hearted manner, but goes straight to the point, and strenuously upholds the sacredness and inviolability of professional secrecy. Duty to the patient, he says, should be the first and paramount consideration. He deplores the apathy and silence displayed by the great medical corporations on the subject, and indulges in a free criticism of some of the evidence tendered during a recent celebrated trial. Dr. Mercier reviews in detail the various exceptions to the general rule which were brought forward at the time, and which aroused so much discussion. With regard to sane patients he will hear of no exceptions, and states that a medical man is not, under any circumstances, justified in revealing the confidence of a patient without the patient's consent. Respecting the communications of insane patients the circumstances are somewhat different, and he concludes that the information obtained from an insane patient may be revealed when, and only when, it is expedient for the welfare of the patient or for the public safety. The whole question will come up for discussion at the annual meeting of the Medico-Psychological Association, and should give rise to an animated and interesting debate.

The *Humanitarian* for April has an interesting article on "The Women of the Pit," by John Pendleton. The life of the woman who helps to supply our hearths with fuel is very different from what it was before the Act of 1842 prohibited female toil in mines, but the pit-brow lassie still exists and, notwithstanding the smallness of the pay, seems to love her calling. Says this writer: "Whether the Legislature will ultimately decide that the pit-brow lass must abandon her work, or whether her muscular help will be superseded by mechanical appliances remains to be seen; but her own verdict is emphatically in favour of the continuance of her industrial life. She prefers it to the enervating work of the cotton mill; in fact, she is so attached to the free, though toilsome, employment on the pit brow, that after she has listened to the love avowal of miner or weaver and entered into the bonds of matrimony she is loth to leave her old career, and if her husband has no objection sometimes resumes her toil on the pit brow."

The April issue of *Knowledge* contains a brief summary of the progress of Chemistry and the Chemical Arts during the Queen's reign by Professor Thorpe, LL.D., F.R.S. This is the contribution for the month to the serial articles dealing with the science of the Queen's reign. He concludes with the pessimistic opinion that, "so far as can be seen, there is no immediate hope that this country will be able to compete with Germany in the manufacture of those products which are the direct outcome of the application of the higher and more recondite branches of chemical science to industry, nor will there be even the prospective hope until our manufacturers as a body bring the spirit of science into their work and show a greater receptivity and a more widespread desire to turn the ever growing development of the science to practical account."

New Inventions.

CELLULOID CYLINDER DRESSING-BOX.

A CONVENIENT means of keeping surgical dressings in an aseptic condition and available for immediate use is sure to have a favourable reception, and most of the qualities requisite for this purpose seem to be combined in a receptacle which has been devised by Messrs. Reynolds and Branson of Leeds. This article is in the form of a tall cylinder, which being made of celluloid is transparent, light, and neat in appearance; moreover it is not liable to be affected by antiseptics nor is it easily broken. The cover of the cylinder is an "air filter," a shallow circular dish, also of celluloid, fitting tightly into the upper part of the cylinder, and filled with cotton wool; the lid and the bottom of this dish are perforated, so that after the cylinder is closed air cannot enter without passing through the cotton wool. The cylinders are meant to be carried in an instrument bag; they are made in two sizes, one being 9 in. deep and 3 in. in diameter and the other 7 in. deep and 2¼ in. in diameter.

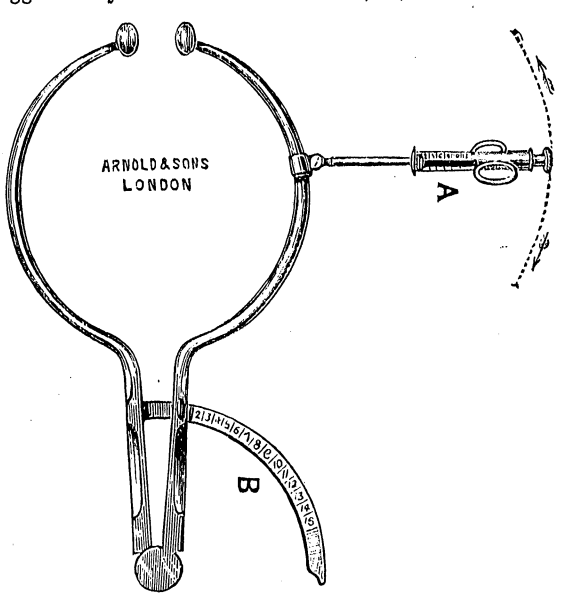
KNIFE FOR SLITTING OPEN THE TONSILS IN CASES OF LACUNAR TONSILLITIS.

IF we carefully examine enlarged or apparently normal tonsils we find in many cases deep crypts or lacunæ. These



crypts frequently contain masses of grey caseous matter, and under the microscope large numbers of various kinds of micro-organisms are seen—often the tubercle bacillus, leptothrix, pneumococcus, Loeffler's bacillus, &c. These organisms frequently cause local or general infection. Most cases of recurrent sore-throat, drain-throat, or even of gouty throat, and many cases of enlarged cervical or bronchial glands, are due to infection which is contained in the crypts of the tonsils. The germ of rheumatic fever is believed by some authors to enter the lymphatics through the tonsils. In many cases of apparently normal tonsils we find quantities of tubercle bacilli in the crypts. In treating cases of diseased tonsils we try to destroy or obliterate the crypts in the tonsils, and thus prevent the accumulation of caseous matter and micro-organisms there. If the tonsils are large, we remove them by the guillotine, the snare, or the knife. If they are small, we try to obliterate the crypts or lacunæ by the galvano-cautery, by caustic, by sharp forceps, or by slitting them open with a knife. The last named is the least painful and most efficacious method. I have had a knife made by Messrs. Down Bros., St. Thomas-street, Borough, in the shape of a strabismus hook with a cutting edge. This is introduced into the crypts and drawn downwards or upwards, thus slitting open the tonsils. The crypts are thus converted into open fissures, and any subsequent accumulation of caseous matter, or of germs, &c., is prevented. The tonsils are then painted with 1 in 1000 perchloride of mercury solution for a few days. From one to three operations on each tonsil generally suffice. At some future time I hope to enter more fully into the methods of infection and the various diseases which can be caused by infection through the tonsils.

ADOLPH BRONNER, M.D.,
Surgeon Bradford Eye and Ear Hospital, Laryngologist Bradford Infirmary.

SPRING PRESSURE GAUGE CALIPERS.

THE illustration shows a pair of calipers made at my suggestion by Messrs. Arnold and Sons, 31, West Smithfield,

and presents an innovation at A, the use of which, though difficult to convey in writing, has, I know from trial, met a distinct want. It may be said that calipers might with advantage be more widely adopted in surgery as a diagnostic aid; for instance, not only in fractures and dislocations and joint diseases, but in some cases of abdominal and pelvic tumours (in the latter instance one limb of the instrument being inserted into the rectum or vagina). Yet my reason for calling attention to the present instrument lies beyond this. I presume others have, as I have, met with abdominal cases, especially in the obese, in which an accurate means of determining the different degrees of resistance to pressure as a diagnostic aid would be desirable, let the locality be the flank, over the cæcum, or elsewhere. Not infrequently, indeed, one is puzzled to know if one part is more resistant than a corresponding part. The instrument I submit will meet this want. If, for instance, it takes in one locality a pressure of 6 lb. of the spring A (note scale) to approximate the limbs so as to register six inches on the scale B, whilst at another locality it takes a pressure of 3 lb. only, then of course the former locality will have a resistance—and a diseased one—of 3 lb. greater than the latter. I hope, therefore, this aid alone may be an apology for another new instrument.

JAMES MACMUNN, L.R.C.P. & S. Irel., L.R.C.P. Lond.
Finsbury-pavement, E.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

THE annual meeting of the Fellows of the Royal College of Physicians of London for the election of President took place on Monday last. Dr. Wilks, in laying down his office gave an address, in which he first dealt with the question of professional secrecy, then reviewed the work of the College during the past year, and finally gave brief obituary notices of the deceased Fellows, the list comprising Sir J. Russell Reynolds, Sir G. Johnson, Dr. G. Harley, Dr. Langdon Down, Dr. W. Cholmeley, Sir B. W. Richardson, Dr. E. Ballard, Dr. C. H. Ralfe, Dr. G. Child, Dr. W. Wilson, Dr. Parry McConnell, Sir Thomas Logan, Dr. C. P. Blake, and Dr. H. Fearnside. At the close of the address a vote of thanks was passed to the President on the motion of Sir Alfred Garrod. The ballot was then taken, when Dr. Wilks received 79 votes; Sir W. Broadbent, 4; Sir R. Douglas Powell, 2; Sir W. Roberts, 1; and Dr. Church, 1. Dr. Wilks was then inducted into office by the Senior Censor (Dr. Church), and briefly thanked the Fellows for having elected him to a second term.

On the motion of the President it was resolved to present a loyal address of congratulation to the Queen on the completion of the sixtieth year of Her Majesty's reign.

Permission was granted to Dr. Hale White to deliver the Croonian Lectures in the Examination Hall, the subject of the lectures being the Means by which the Temperature of the Body is Maintained in Health and Disease.

In response to an invitation from the authorities of the International Medical Congress the President nominated Sir Dyce Duckworth and Dr. Lauder Brunton as delegates of the College to the Congress to be held at Moscow in August next.

A fine portrait of Sir Henry Halford, Bart., President of the College, 1820–44, by Sir Thomas Lawrence, was on view, it having been bequeathed to the College by his grandson, the late Sir Henry Halford.

SOCIETY FOR THE STUDY OF INEBRIETY.—The annual meeting of this society was held on the 8th inst., the President, Dr. Norman Kerr, being in the chair.—Dr. C. R. Drysdale read a paper giving the Results of Experiences of the Successful Treatment of Disease Without Alcohol, a conclusion which Dr. David Walsh thought might be attributable to other factors.—Dr. Kerr protested against the common accusation launched against the medical profession that their prescriptions were "one of the chief causes of drunkenness," he having found that less than ½ per cent. of his cases of inebriety had originated in "doctors' orders."—Dr. Morton, Mr. Riley, and the President discussed a paper by Mr. Cherrill, all concurring in the view that acquired characteristics may be transmitted.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1897.

As the date of the day appointed to be for ever memorable comes near public interest in the scheme of the PRINCE OF WALES'S Hospital Fund grows deeper and deeper; and it is of a twofold character. There is interest as to the amount of the Fund that is to signalise so great an event, and there is almost equal interest in the principles on which it is to be used and distributed. It is impossible as yet to form any precise conception as to the amount of the Fund. It is gratifying to see day after day that it continues to draw large sums and small sums from all sorts and conditions of men. Hospitals have never received subscriptions from so many individuals as those from whom they will have received contributions by the end of this year. This—probably even more than the sum raised—will be the glory and the distinction of the PRINCE'S scheme. HER MAJESTY appeals with a commanding effect to all her people, especially for any object in which the element of suffering or of human sympathy is involved; and she does so all the more effectually through her illustrious son, who has the same strong human sympathies which have been such a powerful factor in HER MAJESTY'S character.

We are not of the number of those who think that the main support of hospitals should come from the poor, or even from those of moderate means. Such classes do a far more creditable thing when they make self-reliant provision for their own ordinary medical wants and come to terms with a medical man of their own neighbourhood, either through the medium of a club or—better still—by private understanding on respectful and self-respecting terms. Such ailments of the mass of the people above the ranks of pauperism have no claim to hospital treatment. It is scarcely reasonable, therefore, to expect much in the way of contribution to hospitals from the classes in question. The hospital is properly the gift of the rich to the poor—of the man who is able in his own comfortable home to provide medical and nursing skill for himself and has enough and to spare to provide the extra medical and surgical skill, with corresponding nursing, which his poor neighbour requires in the emergencies of life when overtaken by grave accident or disease. One good likely to be effected by the PRINCE'S scheme is the bringing into the line of hospital supporters thousands with ample means who have hitherto not contributed—rather, perhaps, from want of thought than from want of heart. It is one of the mysteries in connexion with the support that is extended to hospitals that it is at present given by so few. It is an insoluble puzzle that thousands of well-to-do people should every day of their lives pass hospitals to which they never contribute a farthing, and yet never seem either to sleep or to dine the worse for their neglect. The lists which we see daily and the general sentiment which has been stimulated by the PRINCE'S action lead us to hope that a permanent blow has been struck at this indifference, and that consequently the hospitals of London, in reasonable numbers, and attempting to deal only with fit cases, will henceforth be less straitened in their endeavours to meet the really urgent cases of the classes for whom they were originally intended. If the rich—if even the comfortable men—of the metropolis would do what GUY did 160 years ago, the question of impecuniosity of hospitals would disappear; an efficient central authority would prevent the further multiplication of rival, and particularly of special, institutions; and the one care of administrators would be to accommodate fit cases and to exclude the unfit.

The administration of the Fund and the uses to which it is to be applied give us, we confess, more concern than the amount of it. It would seem from the successive circulars that emanate from the Council of the Fund, and from the somewhat vague terms in which the future form and use of the Fund are spoken of, as if these were still matters for further consideration. There is some wisdom in this vagueness. It gives time to study the trend of public opinion and the real questions that are at stake in any movement for helping voluntary hospitals and placing them in an unassailable position in public opinion. There are two or three principles which doubtless His Royal Highness and his colleagues will bear in mind with advantage. The first of these is to do nothing in promoting their own most popular Fund to damage the existing agencies by which hospitals are supported. It would be a poor effect of the Fund to in any way damage permanently the Hospital Sunday or Saturday Fund. The former especially is an institution which has existed for a quarter of a century and has raised a very large sum of money. It annually appeals to the charity of a number of those who do not more directly contribute to hospitals; and, while it might do much more, it has already done much to improve hospital administration. It should be recognised as a powerful and permanent agent for stimulating hospital charity and wisely supervising its administration. Still less would the PRINCE desire to interfere with the ordinary subscriptions of those whose steady benevolence has been the reliance of hospital treasurers in the past. We have heard whispers of diversion of funds from their ordinary channels into this magnificent and extraordinary channel of 1897. This, of course, is no gain at all to the cause which we all have at heart, and is a poor compliment to the QUEEN and His Royal Highness. It is merely saving with one hand what is given with another—it is robbing Peter to pay Paul. Finally, it would be well, and would powerfully contribute to the success of the Commemoration Fund, if it could be confined and concentrated in respect of the duration of the appeal. The continuation of it into future years will certainly tend to detract from its success and its brilliance as a Commemoration Fund, and to compete seriously with established agencies. Its success is evidently part of the *annus mirabilis* of 1897, and should not be imperilled by having to rely on competition with common methods of appeal and advertisement in ordinary years. We make these observations in sincere sympathy with the general object of the PRINCE'S scheme, and fervently hope that when

Hosted by Google

by its aid the hospitals are freed from the ever-pressing load of debt they will be once more at liberty to pursue their merciful work of relieving the sick and suffering without the temptation, which now too frequently arises, of distributing that relief with too lavish a hand.

THE advertisements and announcements having reference to the QUEEN'S Commemoration in June which meet the eye on every side should serve as a warning that the influx of visitors to London at the time of the festival is likely to be unprecedented. It is impossible to find data for a reliable estimation of the extra visitors which London is to expect, but the million and a half which is freely spoken of does not strike us as being in any way impossible.

How many persons can find accommodation to see the procession? The route is six miles in length, and standing shoulder to shoulder and allowing eighteen inches for each person it would take 15,120 persons to reach the length of the route. Doubling this we get 30,000 as the number for one line on each side for a length of six miles. In order that 1,500,000 spectators may view the procession there must be fifty rows of 15,000 on both sides of the route. It seems scarcely possible that accommodation can be found for such a huge concourse, but that many will have to be content with the enchantment of very distant views, and doubtless London will recall the Rome of CÆSAR, as imagined by our ever-living poet:—

"Many a time and oft
Have you climbed up to walls and battlements,
To towers and windows, yea, to chimney-tops,
Your infants in your arms, and there have sat
The livelong day, with patient expectation,
To see great Pompey pass the streets of Rome."

Few are aware of the enormous elasticity of London and the constant variation in the number of its inhabitants which is constantly going on. The dwellers and workers in the City are ten times as numerous at high noon as they are at midnight, and it is estimated that over a million persons enter and leave the City daily on business of one kind or another. What is true of the "City" proper is also true of central London generally, so that it may be assumed that the machinery now existing for the transport of people is quite adequate for the Jubilee. Ordinary business will be necessarily set aside to a great extent along the line of procession for at least three days previously, and as the Commemoration day is to be a holiday many who would ordinarily visit the City will stop away. After making every allowance, however, there can be no doubt that for two or three days at least London will be choke full, and we are bound to ask whether the over-crowding which will necessarily obtain is fraught with any danger to the public health.

Doubtless, as always must be the case, the ends of some few persons who are "ripe to depart" will be accelerated by the excitement and extra exertion, and it is equally not to be doubted that an average number of casualties will take place, and that some will be made ill by feasting "not wisely, but too well." Beyond this we are inclined to think that the festivities, with all the overcrowding they entail, will not appreciably affect the death-rate. Of all causes which tend to produce a high death-rate overcrowding is by far the most potent, but the ill-effects of it are seldom produced acutely, and it must be remembered that over-crowding in the open air is far less dangerous than over-crowding within four walls and under a common roof.

To be shut up for some hours in a crowded room with a case of infective disease is doubtless very dangerous, and our readers do not need to be reminded of the instances of the infection of judges, counsel, jury, and spectators by prisoners with gaol fever, or of the spread of infant maladies by means of indoor "treats" of various kinds.

The QUEEN'S Commemoration will be unique in the fact that all ceremonial is to be out of doors, and HER MAJESTY deserves the thanks of her subjects for this novel departure from customs which are more honoured in the breach than in the observance. The QUEEN has always manifested what may be called a "living faith" in the value of fresh air. HER MAJESTY has a wholesome horror of close and stuffy rooms, and it is well known that in the summer HER MAJESTY'S breakfast, luncheon, and tea are often served out of doors, and dwellers on the Dee side are aware that no ordinary weather (be it never so "saft" or even snowy) will deprive them of the pleasure of seeing their Sovereign in the well-known wagonette with grey cobs. It is largely owing to this fact that HER MAJESTY'S seventy-eight years sit so lightly upon her, and HER MAJESTY'S example, if loyally followed by her subjects, would have an incalculable influence for good upon the public health.

The difference in the susceptibility of individuals to the effects of foul air is very remarkable. There have been judges, and many, who have lived to a vigorous old age, and have continued to deliver the clearest judgments in the thickest of atmospheres, and who have remained in happy ignorance as to what is meant by foul air. On the other hand, there are many persons who cannot spend an hour or two in a crowded theatre or a crowded church without suffering from subsequent headache or malaise, or without "catching cold," as the inevitable consequence of their imprudence. HER MAJESTY has always manifested considerable intolerance of the atmosphere of crowded places, and it has been one of the penalties of her high position and popularity that every place which she honours with her presence has been "crammed to suffocation." Those who remember the intolerable heat and stuffiness of St. Paul's Cathedral at the Thanksgiving Service of 1872 or of Westminster Abbey at the Jubilee of 1887 will be thankful that in commemorating the sixtieth year of her reign our venerable Sovereign is to be saved from any similar trying ordeal.

AMONG the principal questions likely to engage the early attention of the General Medical Council at its meeting in May will doubtless be the judgment of the Lords of HER MAJESTY'S Most Honourable Privy Council on the subject of the refusal of the General Medical Council at its meeting in November last to accede to the application of the Apothecaries' Hall of Ireland to appoint surgical and, if it pleased, medical examiners also. Our readers will remember that on the first occasion, in 1896, when this subject was before their Lordships after the first refusal of the General Medical Council to assist the Apothecaries' Hall to maintain a position as a licensing body, they advised that the Hall should again approach the Council, asking them

Hosted by Google

to re-consider their attitude and to appoint examiners, not only in surgery, but also in medicine. This suggestion was accepted most willingly by the Hall, and in their next application to the Council for assistant examiners in surgery, while suggesting two gentlemen as examiners in medicine, they expressed their willingness to substitute any other examiners the Council might prefer. The Council in June last, though influenced by four or five unsatisfactory reports of successive inspections and visitations of the examinations of the Hall, was still unprepared to go the length of a direct refusal to appoint the examiners asked for, and, on the motion of Sir WILLIAM TURNER, directed communications to be made to the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Ireland asking them to re-consider their respective positions with a view to a second combination between them such as should maintain an efficient standard of examination. But this well-meant device did not succeed. The Royal College of Surgeons in Ireland declined to enter again upon a conjoint scheme with the Hall; and when the Hall in November last, acting on the advice of the Lords of the Privy Council, asked the General Medical Council to appoint examiners, the Council by a vote of 23 against 2 (the proposer and seconder only) declined. The motion declining to make the appointments was proposed by Dr. MACALISTER and seconded by Mr. TEALE. Dr. MACALISTER in his speech[1] argued that it was so unlikely that the Council would be able to supervise and control the examination effectually after appointing surgical examiners that it would be better to leave the responsibility of such appointments with the Privy Council than for the General Medical Council to accept it. This view was adopted by the large majority of the Council which we have named, but the Privy Council has taken a different view of the question. Their Lordships have notified that, having heard counsel on both sides, their opinion is "that occasion has arisen for the General (Medical) Council to appoint assistant examiners in surgery under the Medical Act, 1886, for the purpose of qualifying examinations to be held by the Apothecaries' Hall of Ireland; and accordingly, in pursuance of the Provisions of Section 19 of the Medical Act of 1886, the General (Medical) Council is directed to appoint such examiners."

This episode in medical history is one upon which it is permissible to dwell for a few moments, and this we do with due respect to the Lords of the Privy Council before whom the matter was laid—viz., the Lord President (the Duke of DEVONSHIRE), Lord MACNAGHTEN, Lord JAMES OF HEREFORD, and Lord RATHMORE—although we are not prepared to find their judgment beyond criticism. We have often pointed out that in the last resort the Privy Council is the authority in law with which the General Medical Council has to reckon, and it is not a little creditable to the General Medical Council and the various medical bodies over whom it has jurisdiction that the Council has administered the Medical Acts for forty years without having come into collision with the Privy Council. There is no evidence now of any want of mutual respect between these two bodies. The opposite conclusion which has been reached by them only expresses their natural difference of standpoint, and time will show whether this difference is one affecting the mere order of procedure or whether it is of deep and serious import. For it would be a serious thing in the eyes of the medical profession if, after patient and costly inspections and visitations by the General Medical Council, an unneeded medical corporation had by the order of the Privy Council to be preserved and to be allowed to compete with other examining boards after its *raison d'être* had ceased in the estimation of the General Medical Council. This result does not necessarily follow from the action of their Lordships in this case, but it seems to be the immediate consequence of their judgment. They recite Section 5 and Section 19 of the Medical Act of 1886 as if the General Medical Council had no discretion in the matter but to appoint examiners for a body in the position of the Apothecaries' Hall of Ireland, and as if they themselves had as little discretion to abstain from notifying the same to the General Medical Council. They seem to have decided that, in the event of the Council not complying with their directions and notifications no responsibility with regard to the appointments rests with themselves. That four gentlemen, however eminent in statesmanship or law, should have such power over a medical body of thirty members, representing the profession and all its corporations, the universities, and the Crown, is indeed a serious fact, and one which will not readily be understood by the public or the medical profession. The General Medical Council, as a non-legal body, naturally sees in the words "if they see fit" a certain discretion as to its function of appointing additional examiners. But the judgment of their Lordships seems to abolish all discretion in the matter. It is time, in the interest of common sense, that either these words should cease to be used in the Acts of Parliament or that they should be allowed their natural meaning.

Meanwhile it seems to us to be a very regrettable matter that the General Medical Council, which may surely at least be credited with a desire to act in this respect with a due regard to the best interests of both the medical profession and the public, should have received such a rebuff at the hands of the Privy Council.

[1] THE LANCET, Nov. 28th, 1896.

Annotations.

"Ne quid nimis."

THE PORT OF LONDON.

THE half-yearly report of Dr. Collingridge, medical officer of health for the Port of London, shows that 14,422 vessels were visited and inspected in the Port of London during the half-year ending Dec. 31st last—a considerable increase on the number for any previous half-year. Of the number stated 82·4 per cent. were British and 9·7 per cent. Scandinavian. Forty-eight sick seamen were referred to hospital. Attention is drawn to a sanitary defect frequently met with in these days of iron and steel ships—namely, the condensation of moisture which occurs on the under side of decks over forecastles, the result being that this moisture runs down on to the bunks below, and it is no uncommon thing to find men's bedding and clothes saturated from this cause, a serious matter as affecting the

Hosted by Google

health of seamen who are well known to suffer beyond the average from rheumatism and its train of concomitant diseases. A coating of granulated cork on the iron is good as a palliative procedure, but the only effectual method of dealing with the nuisance is to have a wooden deck over the iron and the under surface completely lined with the same material close up to the deck, all beams being encased. The instructions to surveyors last issued by the Board of Trade prohibited the placing of bunks under an unsheathed deck, but the operation of this section was postponed. Another matter in the port which calls for attention is the condition of the cabins of lighters and other "dumb" craft. The Merchant Shipping Act and Canal Boats Act provide for the comfort of persons living in craft registered under these Acts, but in the case of lighters, though the cabins cannot strictly be considered as dwellings, they have to serve as temporary habitations, often for considerable periods. The Port Sanitary Authority is now, since the Public Health Act, 1896, practically the health authority for the port, and its medical officers have discretionary powers as to the detention of vessels in reference to the diseases named. During the half-year eighty-eight cases of infectious disease came under the notice of the authority's officers. Two cases of plague, the diagnosis being verified by bacteriological examination, were admitted into the Seamen's Hospital in 1896. The first case was that of a native of Bombay admitted on Sept. 19th, who had apparently been ill for twelve days or less, and who died five hours after admission. The other case was that of a patient ill for four days, who was admitted on Sept. 29th and who died on Oct. 3rd. Careful instructions were given to the boarding medical officers as to dealing with suspected cases found on vessels. The order of the Local Government Board requiring in certain circumstances the disinfection of rags imported from abroad has been rescinded. Details of nuisances dealt with are given, and in consequence of the continuance of the practice of pumping filthy bilge-water into the docks and river a special notice has been published as a warning. Particulars are given of some cases of overcrowding, and especially insanitary condition, found on some foreign vessels. At the hospital of the authority 29 patients were treated during the half-year, of whom only 4 died; the average number of patients under treatment daily was 3 6, and the average number of days spent in hospital by each patient was 21·7. A considerable number of seizures of unsound food was made during the six months, comprising 2758 carcases and 1469 pieces of mutton and lamb, 14 quarters and 30 pieces of beef, 2 tons of bacon and hams, 18 casks of horse beef, 496 tins of meat, 45 cases of salmon, 2909 lobsters in jelly, 41 cases of desiccated soup, 4270 tins and 74 cases of rabbits, 198 cases of condensed milk, 7100 crates of bananas, 5000 boxes of oranges, 146 packages of fruit and vegetables, sundry small parcels consisting of apricots, bacon, brawn, cheese, chestnuts, confectionery, currants, hams, kidneys, olives, ox tails, peaches, persimmons, pickles, pines, suet, sultanas, tomatoes, tongues, tripe, &c. An additional new launch has been added to the service of the Port Sanitary Authority, whereby the duties of inspection have been greatly facilitated, though it has only been at work since September. The number of canal boats inspected was 668, a slight increase; 114 boats were found to be in some way infringing the regulations. The number of women and children carried shows a slight increase for the past two years, being to some extent due to the great frost of 1895 which, paralysing the canal traffic as it did, compelled many boatmen to break up their homes on shore and take their families afloat — a serious matter, as canal boats are not a desirable habitation from either a moral, sanitary, or educational view for women and children. A new order respecting cattle ships was issued on Dec. 8th last, which makes several concessions to ship-owners for which they have striven for some years. Reference is made to the report by the medical officer of the Local Government Board on oyster culture in relation to disease, several oyster lays being within the jurisdiction of the Port Sanitary Authority, though it does not appear that a sanitary authority has any definite power to act in the matter of oysters at these places. The subject is considered an important one, and a strong case exists for proper systematic supervision.

ROYAL COMMISSION ON TUBERCULOSIS.

THIS Commission sat at 7, Whitehall-place on April 8th and 9th, Sir Herbert Maxwell, Bart., M.P., being in the chair. The other Commissioners present were Dr. R. Thorne Thorne, C.B., F.R.S., Professor G. T. Brown, C.B., Mr. Shirley F. Murphy, Mr. T. Cooke-Trench, and Mr. J. Speir, Evidence was heard from the following gentlemen:—Dr. Smyth, medical officer of Naas dispensary district, as to the subject of tuberculosis in the small towns and rural districts of Ireland; Mr. Thomas Nuttall, representing the Central and Associated Chamber of Agriculture, as to his experience of the prevalence of the disease in the district of Leicestershire; Mr. J. Lang and Mr. Scarlett, of the Paisley United Fleshers' Society, as to the action of the local authority in condemning carcases affected with tuberculosis, and the system of insurance adopted by the butchers to protect themselves from the losses sustained in consequence of such action; and Mr. J. Bell, President of the Carlisle and District Butchers' and Insurance Association, as to similar action in Carlisle.

MEDICAL FEES IN AMERICA.

MEDICAL fees in America, taken all round, are higher than those in England. It has been computed that there are two or three consultants in New York who make £20,000 a year, five or six who make £10,000, and several who make £5000 and upwards. Locality has, of course, a great deal to do with the rate of fees, for a man who settles in the country naturally does not expect to have so large an income as one who takes a house in a rising town or in a large city. Fees in New York are somewhat higher than elsewhere in America. As a rule, in that city a family attendant receives an amount varying from $2 to $5—i.e., from 8*s*. to £1—per visit, and the average fee of those whose practice lies wholly among the wealthy is from $5 to $10. Consultants' fees range from $10 to $25. Visits at a distance from home are at the rate of from $10 to $20 per hour, not including travelling expenses, and a fee of $25 for the consultation itself. Fees for surgical operations run from $100 into several thousands. In the lower district of New York a practitioner must be content with a fee of $1 (i.e., 4*s*.) for a home consultation and from $1 to $1.50 for a visit. In the other large towns of America the ordinary fee for advice is from $1 to $2, and never less than $0·50; for a visit the charge is from $1 to $5, and never less than $1. Midwifery fees vary from $10 to $50. The fact must also be borne in mind that in the States a medical man rarely does his own dispensing, and the druggist charges for making up the requisite medicine a sum of at least $0.50, so that in all cases advice and medicine will cost the patient at the lowest estimate $1. In many of the smaller towns a physician is glad to give advice at his house for $0.50 (i.e., 2*s*.) and to make a visit for $1. Such an institution as the cash practice, where advice and medicine may be had for 6*d*. or 4*d*., is absolutely unknown in America, and it may be asserted without fear of contradiction that the average income of a medical man there is higher than in England. One drawback, however, is attached to the practice of medicine in the States which does not exist to the same extent in Great Britain, this being the greater difficulty

Hosted by Google

experienced by American physicians in collecting debts due to them, for practice is carried on almost wholly on the credit system and it often happens that a patient after consulting a specialist does not leave his fee on the table. Why fees in the States should be generally so much higher than in England is a matter somewhat difficult to comprehend. Less competition cannot be the cause, for in the States there is one medical man to every 500 persons, whereas in England there is only one to every 1500. The working classes in America receive larger wages than in Great Britain, and no doubt this partly accounts for the higher medical fees, but a still more potent reason is the fact that in America the members of the medical profession stand well together and are resolved to resist as vigorously as possible any attempts to lower the rate of fees.

COOKERY AND FOOD EXHIBITION.

THE Cookery and Food Exhibition, which is held annually under the auspices of the Universal Cookery and Food Association, instituted and promoted to extend a better knowledge of the various substances used as food and the best and most economical method of cooking, will be opened on Wednesday, May 12th, at the Niagara Hall, St. James's-park, London, S.W., and will remain open till the following Wednesday. The exhibits will be classified under the headings of Education in its connexion with Cookery; Plain or Household Cookery; Army, Navy, and Mercantile Marine Cookery; Artistic Cookery; Cookery Teachers' Competition; Artistic Confectionery, &c.; Bread and Pastry; and Provisions, &c. Various demonstrations and lectures will be given. This is the tenth exhibition of the kind that has been held, and we wish it every success. Bad cooking is answerable for some of the ills of the flesh, and to any efforts to improve what is almost a neglected art in this country, especially amongst the poor, we give our hearty support.

PHOTOGRAPHIC ENERGY OF THE LIGHT OF FIRE-FLIES

A VERY interesting investigation of the luminous and other radiations emitted by fire-flies has just been published in the ninth volume of the *Journal of the College of Science*, Imperial University, Tokyo, Japan. The author, Mr. H. Muraoka, who writes in German, is Professor of Physics at Kyoto. He mentions that the spectacle produced by the fire-flies about the middle of June is one of the sights of the place, and he states that the present inquiry was suggested to him by the resemblance of their light to that of fluorescent bodies, some of which have been shown by H. Becquerel to emit radiations possessing properties analogous to those of the Roentgen rays. The flies are most luminous from about 6 P.M. to 11 P.M. The experiments were made by placing a number of them, varying from 300 to upwards of 1000, in a small flat box in which they were confined under a net made of hemp ("deren Wegfliegen mit einem Hanfnetz verhindert wurde"). The box also contained a photographic dry plate, in contact with which were plates of various metals (copper, aluminium, zinc, and brass), all of similar thickness, sheets of cardboard, both entire and also with cruciform patterns cut out of them, being sometimes interposed between the sensitive plate and the metal and sometimes used alone with the sensitive plate. Thin wooden boards were also employed for the same purpose. The sensitive plate and the objects in contact with it were wrapped in several thicknesses of black paper and left in the box with the flies for two nights. The experiments were made in a photographic dark room, sunlight and artificial light being carefully excluded. The sensitive plates, though thus wrapped up, and additionally protected by metallic plates and layers of cardboard, gutta-percha, cloth, silk, &c., were always more or less blackened. Professor Muraoka makes frequent reference to the papers published in *Nature* in the early part of 1896 by Dr. John Macintyre of Glasgow and Mr. J. J. Thomson. His experiments led him to the following conclusions:—1. The light of the flies in its original state behaves like ordinary light. 2. The light contains rays which pass through cardboard, metal plates, &c., and possesses properties analogous to those of Roentgen rays or Becquerel's fluorescent rays. 3. When the photographic plate is covered with layers of cardboard it presents an appearance which calls to mind the permeability of iron to magnetic lines of force. 4. The properties of these "filtered" rays appear to be influenced by the materials through which they have passed, perhaps by the thickness of the materials. 5. The properties possessed by the radiations and specified under No. 2 are apparently non-existent, or at least undiscoverable until after "filtration." The Roentgen rays are similarly undiscoverable until after "filtration"—i.e., through the glass of the Crookes's tube—and "filtration" may, perhaps, afford a means of rendering the x rays homogeneous. 6. The "filtered" fire-fly rays undoubtedly admit of reflection. Refraction, interference, and polarisation could not be demonstrated, but Professor Muraoka is of opinion that they take place. 7. The "filtered" firefly rays seem to resemble Becquerel's fluorescent rays in possessing properties intermediate between the ultra-violet rays and the Roentgen rays. The volume of the *Journal of the College of Science* in which this article appears contains over 200 pages; all the other papers are in English, and are mostly chemical, except four, the subjects of which are electricity, magnetism, geology, and astronomy.

TRICUSPID STENOSIS.

TRICUSPID stenosis is a disease of some rarity. Dr. James B. Herrick, having found three cases in the post-mortem room not diagnosed during life, writes on the subject.[1] He has collected all the cases published since Leudet's thesis, which appeared in 1888 and gave a complete bibliography to that date. To the 117 cases (of which 114 had records of necropsies) furnished by Leudet the writer is able to add 40 with necropsies. He gives abstracts of most of these, and on the basis of the whole 154 cases constructs an account of the disease. But he has little to add to Leudet's conclusions, which must still be the foundation of future work. Tricuspid stenosis may be congenital, and then it is either the result of a develop mental defect or of intra-uterine endocarditis. It is usually accompanied by other abnormalities—pulmonary stenosis, defects in the inter-ventricular septum, patent foramen ovale and ductus Botalli. The symptoms are cyanosis, clubbed fingers, and diastolic and systolic murmurs. Few patients survive until twenty years of age. In the acquired form antecedent rheumatism occurred in 30 per cent; but there were also doubtful cases, so that for this and other reasons the relationship is understated by the writer. Leudet, indeed, estimated it at 50 per cent., which appears to be nearer the truth. The age at death of the greatest number affected with the acquired form was between thirty and forty years. As in mitral stenosis, the disease was more prevalent in females than males, the proportion being 114 to 32. The tricuspid leaflets are generally found adherent by their free borders. The opening may admit only one finger-tip or less. Naturally, with the stenosis there is regurgitation. The disease is rare as an isolated lesion; in Leudet's 114 cases this occurred in only 11. Mitral stenosis was by far the commonest concomitant (78 cases). Mitral and aortic stenosis occurred in 21 cases, and pulmonary stenosis in 3. The right auricle is usually enlarged, sometimes considerably, "like a

[1] Boston Medical and Surgical Journal, March 18th, 1897.

Hosted by Google

supplementary heart." Where the stenosis was marked there was usually a small right ventricle, and this in spite of the fact that there was also mitral stenosis. Commonly, however, the combined lesions produce general enlargement of the heart. The symptoms are those common to valvular disease. Dyspnœa may be extreme. Cyanosis is generally marked, with perhaps œdema. The pulse, from deficient supply of blood, is small. Presystolic venous pulse is generally seen, often with systolic from concomitant insufficiency. Percussion reveals an enlarged right heart, and commonly left also, from mitral or aortic disease. Dulness may commence as high as the second space to the right of the sternum, suggesting auricular enlargement. Thrills are at times present. The murmur is diastolic, heard best over the right fifth and sixth cartilages, but it is frequently inaudible. The diagnosis presents great difficulty; only 6 of the 114 cases were recognised during life. The disease may be suspected in a female who has mitral stenosis with a history of dyspnœa, palpitation, œdema with remissions, and cyanosis, especially if persistent. Right auricular enlargement is very suggestive. If, in addition, there is a presystolic or diastolic murmur heard best over the ensiform or right fifth and sixth cartilages, particularly if this differs from the mitral in character, or if there is an area between the two where none is heard, the diagnosis is reasonably certain. The prognosis in general is bad, but must depend on all the circumstances of the case. It should be remembered, however, that a patient may live to sixty-five years. The treatment is similar to that of heart disease in general.

A CHILD KILLED BY FERRETS.

AT Bromsgrove, on the 6th inst., an inquest was held on the body of Ernest Lewis, aged two years. On March 26th the deceased and four other children, whose ages ranged from five months to seven years, were left in bed, locked up in a house at Dodford, whilst the parents went to market. Two ferrets which were kept in the house broke loose, and getting upstairs attacked the sleeping children. The eldest boy repeatedly threw the animals downstairs, but as there was no door to the bedroom they returned. The boy Ernest sustained a number of severe bites, to which he succumbed. A large part of his mouth and nose were eaten away. The medical man stated that all the children except the eldest would be permanently marked. The jury blamed the father for not taking proper precautions to secure the animals. Such is the matter-of-fact account furnished by some of the daily papers of this gruesome tragedy. The sufferings of these unfortunate children both from physical pain and terror must have been intense and long continued. It is difficult to conceive anything more ghastly. It does not appear to be generally known how very ferocious these beasts are, especially when hungry. To the censure of the jury on the father we would add that the animals should not have been kept in the house at all. We trust the case will serve as a warning; but we fear it may not attain the publicity that it should.

THE SMOKE NUISANCE IN SHEFFIELD.

THE air of Sheffield is proverbially in a chronic state of murkiness, and the town suffers considerable reproach on this head. But in a most comprehensive report on the causes of prevention of smoke recently drawn up by Dr. Littlejohn, the medical officer of health, he very properly points out that in contrast with other towns Sheffield is seriously handicapped by the fact that it contains a much more closely packed smoke-producing area. The amount of coal consumed in Sheffield annually is about one and a quarter million tons, and this within an area of thirty square miles. In London in 1892 the amount consumed was the same, but the area of distribution is 235 square miles, so that were London factories brought into a square whose sides were three miles distant north, east, south, and west of Charing-cross, it may be assumed that the conditions of the metropolitan atmosphere would be much the same as that of Sheffield. The amount of sulphuric acid corresponding to the amount of sulphur in that quantity of coal would amount to 37,500 tons, so that in Sheffield, while the sulphuric acid deposited in the rain would amount to 1000 tons to the square mile, in London it would only be equal to 140 tons. In other words, London receives on the ground just as much sulphuric acid as Sheffield, but over a larger area and consequently more diluted. It is probable, however, that London is more favourably situated than is Sheffield for the removal of smoke. It is, no doubt, the continued prevalence of winds during the last few winters—and London has no barrier against the onset of winds in any direction—which has resulted in the notable absence of fogs in the metropolis of late. Dr. Littlejohn, we are glad to see, points out to the Sheffield Health Committee that much more may be done by efficient control and regulation towards mitigating the evil still further, and his report is a valuable contribution on the subject.

PARISH MORTUARIES.

WE have many times insisted upon the paramount necessity which exists, especially in thickly populated town parishes, for the erection of properly appointed mortuaries. To say nothing of the question of decency and reverence it is acknowledged by every one that the presence of a corpse in a small room, often less than eight feet square and inhabited day and night by several persons, is not conducive to health. A praiseworthy attempt is now being made by the vicar of the very poor parish of St. Augustine's, Stepney, to raise a fund for the erection of a decent and well-fitted mortuary for the reception of the bodies of those who die in his parish. That such is needed is obvious when it is remembered that the parish can be walked in its length in four minutes and across in two minutes, while the population is 7500. A sum of £915 has already been raised and £585 are required in addition. Donations may be sent to The Vicar, St. Augustine's, Stepney, E., and we cordially commend this scheme to the generosity of those who have any money to spare. It must be remembered that the mortuary will also serve for the needs of adjacent parishes which are quite as crowded as is St. Augustine's.

PLAGUE AT HONG-KONG IN 1896.

WE have received a copy of the Blue-book dealing with this epidemic. Plague is at all times an interesting disease, and is doubly so to us at the present juncture. The report is drawn up by Dr. Wilm, a staff surgeon in the Imperial German Navy, whose services were kindly placed at the disposal of the Colonial Government by the admiral in command of the German Asiatic Squadron. He was placed in charge of the Kennedy Town Hospital and the bacteriological laboratory which was established there in May, 1896. During his term of office he treated 300 cases of plague and examined the bodies of 867 persons who had died from the disease. In most of the cases there were no prodromata, the period of incubation was usually from three to six days, but in one instance apparently fifteen days. There was intense prostration and delirium with fever, the temperature ranging from 100·6° F. to 106° F., but a high or low temperature seemed to make no difference in the fatality. The fever lasted from six to ten days, rising from the third to the fifth day, and then gradually falling to normal; but later a secondary fever appeared, apparently

Hosted by Google

due to some septic absorption from buboes. Petechiæ—probably the "tokens" which Boghurst and other seventeenth century writers mention as of unfavourable import—only appeared in 3 per cent. of the cases, and these very severe ones. The mortality among hospital patients was 73 per cent., and among Europeans 50 per cent. Convalescence was very slow. From a series of bacteriological experiments Dr. Wilm concludes that infection is possible through the skin, but that this is uncommon; the most frequent mode of invasion is by the alimentary tract. The bacillus is very sensitive to heat, light, and fresh air, and plague, like typhus, would seem to be essentially a filth disease. The treatment employed was merely symptomatic, but Yersin's serum treatment as used by himself in Canton is said, if employed within the first three days, to have met with great success. Dr. Wilm gives a scheme of prophylactic measures, chiefly hygienic—strict cleanliness, destruction as far as may be of infected material, and special attention to the water-supply being the most important points. We have only given the barest outline of Dr. Wilm's researches, but the whole Blue-book is deserving of the most careful attention, and the thanks of everyone are due to Dr. Wilm, and also to his superiors for the use of his services. The report is translated by Dr. Maurice Eden Paul.

LORD LISTER AND HIS FORMER HOUSE SURGEONS AND DRESSERS.

NOT the least interesting of the many expressions of esteem and regard which have been offered to Lord Lister on his elevation to the peerage is the banquet which is being organised by those who have served under him in Glasgow, Edinburgh, and London as his house surgeons, clerks, and dressers, and who have therefore been intimately associated with him in the spread of his discoveries and the elaboration of his principles. The dinner will take place at the Café Royal, Regent-street, on Wednesday, May 26th. It will be presided over by Professor Joseph Coats, and will be limited to those who have served under Lord Lister as house surgeons, clerks, or dressers, as its intimate character is to be strictly preserved. Lord Lister entered on his duties at Glasgow in 1861 and at Edinburgh in 1869, so that considerable difficulty has been experienced in obtaining the names and addresses of his assistants in the early period of the thirty-two years during which he was a teacher of clinical surgery. We are asked to say that all who have filled any of the offices mentioned should communicate at once with the honorary secretary of the dinner committee, Dr. St. Clair Thomson, 28, Queen Anne-street, London, and should mention the year in which they held office, and it is hoped that this information will be given whether they are able to attend the dinner or not, as it is desired for sentimental reasons to draw up a correct list, in chronological order, of the gentlemen who have been privileged to assist practically in the development of antiseptic surgery.

THE FEEDING OF YOUNG CHILDREN.

ERRORS in the feeding and management of young children are responsible for much of the sickness, suffering, and mortality of early life, and while some parents who ought to know better are culpable of gross ineptitude in the care of their offspring, there are many among the poorer classes who are quite ignorant of the principles which should underlie the rearing of young children. The Sanitary Committee of Brighouse, Yorkshire, have had prepared by their medical officer, Dr. Meredith Young, a set of rules, based largely upon the Obstetrical Society's recommendations, printed on a card with a loop of tape attached for the purpose of hanging up for reference. It is proposed to distribute these rules by the agency of the local registrars of births and deaths. This is certainly a step in the right direction, and we should like to see its more general adoption; but if the information could be compressed, printed in larger type, and adapted more to the requirements of the very poor, the value of the plan would be increased. It is useless to tell a certain class of the population that children should sleep in large rooms, for the simple reason that the poor cannot afford to rent large rooms; and we doubt very much if this class of the community understands anything by being told that the infant's bath should be at a temperature of about 90° F. As warm as could be comfortably borne by the mother's elbow would be a far preferable direction. Apart, however, from these slight defects the card should certainly prove to be of use.

THE NEW BRITISH HOSPITAL AT CANNES.

A PROPOSAL was made some five years ago to erect a permanent British hospital at Cannes, and the building, if not already *un fait accompli*, will, we hope, be so shortly. On April 8th, the first stone of the new buildings was laid by His Royal Highness the Prince of Wales at Sunny Bank, in, as his Highness himself expressed it, "this charming Cannes—in this beautiful country." The temporary buildings which at present constitute a British hospital were opened at the end of 1893, since which time about 100 patients have been successfully treated. The new buildings, as Sir Sydney Waterlow stated in his address to the Prince of Wales, will provide ten beds for ordinary cases and five beds for contagious cases which will be completely isolated, and the whole will cost about 55,000 fr. Such an institution is much needed, and will no doubt be greatly appreciated by many.

THIOSINAMINE IN KELOID.

DR. RICHARD C. NEWTON[1] reports a case of keloid treated with hypodermic injections of thiosinamine. We are reminded that this drug, an allyl-sulpho-urea procured from the volatile oil of horseradish by the addition of ammonia, was originally used by Hebra as an absorbent of exudates in corneal opacities and in lupus, and later by Dr. Tonsey of New York in the treatment of keloid. The amount injected by Dr. Newton was from fifteen to twenty minims of a 10 per cent. solution. After repeated injections a diminution both in size and hardness of the keloids was observed. In another case of tight contraction of the skin and subcutaneous tissue after an extensive burn a marked increase in mobility with softening of the affected tissue followed the use of these injections. Recovery from a disease like keloid, we fear, is hardly to be expected under any method of treatment save excision, but something will have been gained if further experience of thiosinamine should confirm the results already claimed for it as an absorbent of scar tissues.

THE JENNER SOCIETY.

WE have before us the report of the executive committee of the Jenner Society for the year 1896, a society which was founded in Gloucestershire at the time that the city of Gloucester was being so severely visited by small-pox, the main object of the organisation being the dissemination of knowledge concerning vaccination, which was sadly wanted there. The society thus formed comprises many influential persons, and, thanks to the untiring energy and enthusiasm of its moving spirit, Dr. F. T. Bond, the honorary secretary, much useful work has been done during the first year of its existence. It was fitting that such a society should have its origin in the county where Jenner lived and worked, but we would fain hope that the good work thus

[1] New York Medical Journal, March 20th, 1897.

Hosted by Google

inaugurated may be extended by the inclusion of members from all parts of the kingdom. The report speaks in no uncertain tones upon the tactics and objects of the Anti-vaccination League, and declares that not to oppose "such an organised and aggressive conspiracy against the best interests of humanity would be an abnegation of duty." Yet it is plain that if such opposition is to be commensurate with the operations of the Antivaccination League it will be necessary to widely enlarge the scope and work of the society. If therefore the Jenner Memorial movement can only be devoted to the prosecution of research in the field in which Jenner was the pioneer, we would ask whether it might not be wise to meet the agitation against vaccination by an active propaganda undertaken by a national association which would have the support of all who love truth and value the benefits conferred upon mankind by the introduction of vaccination.

THE CONDITION OF THE PORTSMOUTH SLUMS.

CONSIDERABLE stir has been made in Portsmouth by a report issued by the "Social Reform Society" on the slums of that extensive town. It declares that the society recently instituted an inspection, and instances as a sample of its findings a yard of twelve houses, all badly out of repair and in a filthy condition, with two waterclosets only, and these without water. Another court contained eleven houses, the rooms in which were said to be mere boxes, 8 ft. square by 7 ft. high, and all in a dirty and insanitary condition. The rooms in thirteen houses in a third court were 9 ft. by 7 ft. 6 in. They were in a bad state of repair, and in each case the watercloset was in the cellar under the only living-room, and there was no ceiling to either watercloset or cellar. Assuming that these facts are correct, the reflection upon the sanitary authority is indeed a serious one. Investigations by representatives of a local paper have resulted in the discovery of similar instances of filth and overcrowding, and the matter is certainly one that should be thoroughly examined into.

THE HEALTH OF THE ARMY IN INDIA.

AFTER the meetings that have taken place at the Royal United Service Institution, and the reading of a paper by Major C. B. Mayne, R.E., with a long discussion thereon, it was only to be expected that a good deal of correspondence would follow in the public journals. There is at present, however, a lull in the discussion. The real fight will ensue when the proposals of the Government of India reach this country. Meanwhile, the general impression in India, derived from the telegraphic summary of Lord George Hamilton's despatch to that country, seems to be that the Secretary of State's proposals will prove quite inadequate; while, on the other hand, the opponents of all legislation in this country regard the despatch as going too far or are suspicious that it is intended to prove the proverbial "thin end of the wedge" for the subsequent introduction of all kinds of objectionable measures. The British Committee for the Abolition of State Regulation of Vice in India are actively engaged in sharpening the old weapons in their armoury and in printing and distributing their productions on the subject. No useful purpose will be served at the present moment by occupying our readers' attention with the matter. The profession, as represented by the Royal College of Physicians of London and the Royal College of Surgeons of England, have already spoken with some authority, and "what we have written we have written." This much, however, it is necessary to say. Any proposals that are made by the Government have reference to the British army in India only. Anyone interested or taking part in the controversy should refuse to step outside those limits. There is no pretext for now saying that it is intended to re-introduce the Contagious Diseases Acts into this country. It is the present state of health of the European force in India, and how best to protect or safeguard it against existing or prospective evils, that has now to be considered. The Secretary of State has been most moderate and guarded, it seems to us, in his despatch. We have sufficient confidence in the fairness and wisdom of the majority of people to believe that they will recognise the present lamentable state of things and the dangerous consequences that will ensue from their continuance or probable extension. Let the moderate men of all parties then honestly consider what remedial measures are at once prudent and practicable under the circumstances.

THE MÜTTER LECTURESHIP OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

THE next course of lectures, ten in number, instituted by the late Professor Mütter, the subject being "Some Point or Points in Surgical Pathology," are to be delivered during the winter of 1899–1900 before the College of Physicians of Philadelphia. The remuneration is 600 dollars. The lectureship is open to the profession at large, and applications for the post stating in full the details of the proposed lectures must be sent in before Oct. 1st, 1897, to the Committee of the Mütter Museum. The chairman is Dr. J. H. Brinton, corner of 13th and Locust streets, Philadelphia, Pa.

AT a meeting of the Incorporated Society of Medical Officers of Health held at No. 197, High Holborn, W.C., on Friday, the 9th inst., Mr. Edward Seaton, M.D., F.R.C.P. Lond., F.C.S., medical officer of health of the administrative county of Surrey, was unanimously elected President of the Society for the session 1897–98. At the same meeting a resolution was adopted to present a loyal and dutiful address of congratulation to Her Most Gracious Majesty the Queen on the occasion of completing the sixtieth year of her reign.

IT is stated that Lord Llandaff (Mr. Henry Matthews) has accepted the chairmanship of the Royal Commission on Metropolitan Water-Supply. The inquiry will refer to financial considerations, prospective requirements, the constitution of new powers of control, the possibility of connecting two or more different systems as occasion may require, and the division into water districts.

THE Home Secretary has selected Dr. H. Smalley, of H.M. Convict Prison, Parkhurst, to fill the post of Medical Inspector of Local and Convict Prisons, vacant by the resignation, through ill-health, of Dr. R. M. Gover. The appointment is one that is likely to be received with general satisfaction throughout the prison service.

A MEETING to promote the objects of the Hospital Reform Association will be held in the Grand Hotel, Birmingham, on Wednesday, April 21st, at 4 P.M.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The annual meeting of the Royal London Ophthalmic Hospital, Moorfields, was held in the institution on March 30th, Sir John Lubbock presiding. The report for the past year showed that there had been 2006 in-patients admitted; there were also 26,074 out-patients, who made 130,370 attendances. The new buildings in the City-road were being rapidly proceeded with, and the Prince of Wales had promised to lay the foundation-stone shortly after Easter. The income for the year was £4809, and the total expenditure was £7770.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

VIII.[1]

KENT WATERWORKS COMPANY (*concluded*).

Present State: General Description.

THE whole of the water supplied by the Kent Waterworks Company is obtained from deep wells and is delivered direct to their customers. There are therefore no depositing reservoirs and no filter beds. The reservoirs of the company are for the temporary storage of water. The stations of the company are: Deptford, wells, pumping station, reservoirs, and offices; New Cross, reservoir; Woolwich Common, reservoir; Plumstead, well and pumping station; Plumstead Common, reservoir; Greenwich Park, reservoir; Chislehurst, reservoir; Shortlands, wells and pumping station; Crayford, wells and pumping station; Dover-road, Shooter's Hill, pumping station; Shooter's Hill, reservoir and standpipe; Farnborough, wells and pumping station; Cowlass Hill, Farnborough, reservoir; Dartford, reservoir; Layham Farm, West Wickham, reservoir; Knockholt, reservoir; Wilmington, wells and pumping station; Westerham, well, pumping station, and reservoir; Betsom's Hill, reservoir; Pilgrim's Way, well and pumping station; and Eltham, reservoir. There are two wells under construction.

Deptford (see A on Map).—The station at Deptford is on the site of the original works of the company; part of it is to the east and part to the west of the River Ravensbourne. The part on the west side of the river consists of the offices of the company, the engineer's house, a well called the Garden Well, the old engine house, and a large garden containing the reservoir which was formerly used. The Ravensbourne is crossed by a bridge, on the site of the old water-wheel which was used for pumping. The fall in the Ravensbourne at this point is not now made use of. To the east of the river there is an enclosed space containing two wells (the New Well and the Bath Well), engine houses, and two covered reservoirs. This is the site of the filter beds which were used when the river was the source of the water-supply.

The *Garden Well* derives its name from its situation. The ground level here is 20 ft. above ordnance datum. The depth of the well is 100 ft., the diameter at the top is 15 ft., and at the lower part 12 ft. The upper 15 ft. are lined with brick, the lower part is lined with iron cylinders. There are some headings in this well and a bore-hole. The water from this well is pumped by some of the original machinery put up by Boulton and Watt. There are two engines of 50 horse-power (nominal), and these work force-pumps, which raise 42 gallons per stroke and work at about the rate of sixteen strokes a minute. The steam is generated by three Cornish boilers. The water is pumped to the high-level district in connexion with the reservoir on Woolwich Common.

The *New Well* was sunk in the year 1868. It is 100 ft. in depth and has headings. It is lined with iron cylinders to a depth of about 75 ft. The water is pumped by two Cornish engines; of these one works a lift-pump, which raises 300 gallons per stroke, and the other a force-pump, which distributes 200 gallons per stroke. The latter works against a head of 180 ft. and pumps the water to the reservoir at New Cross. The steam is generated by five Cornish boilers working at a pressure of 35 lb.

The *Bath Well* gets its name from a neighbouring street, Cold Bath-street. It was sunk in the year 1874. The depth of the well is 100 ft. and it has headings which extend for 80 ft. to a bore-hole which is situated beneath a disused well. The diameter of the well is 10 ft. and the upper part is lined with iron cylinders to a depth of 70 ft. The water is raised by a Cornish engine (brought here from Charlton, dated 1859) which works a lift-pump and a force-pump. The lift-pump raises 240 gallons per stroke from the well, and of this water so raised the force-pump lifts 100 gallons per stroke to Greenwich Park, working against a head of from 150 to 160 ft. The remainder of the water raised by the lift-pump flows to the covered reservoir. The steam for the engine is generated by three Cornish boilers working at a pressure of 35 lb. Near the Bath Well is a disused engine house.

There are two reservoirs capable of storing 2,000,000 gallons. The reservoirs are covered by concrete arches built on brick walls, and the arrangement of the walls insures a circulation of the water in the reservoir.

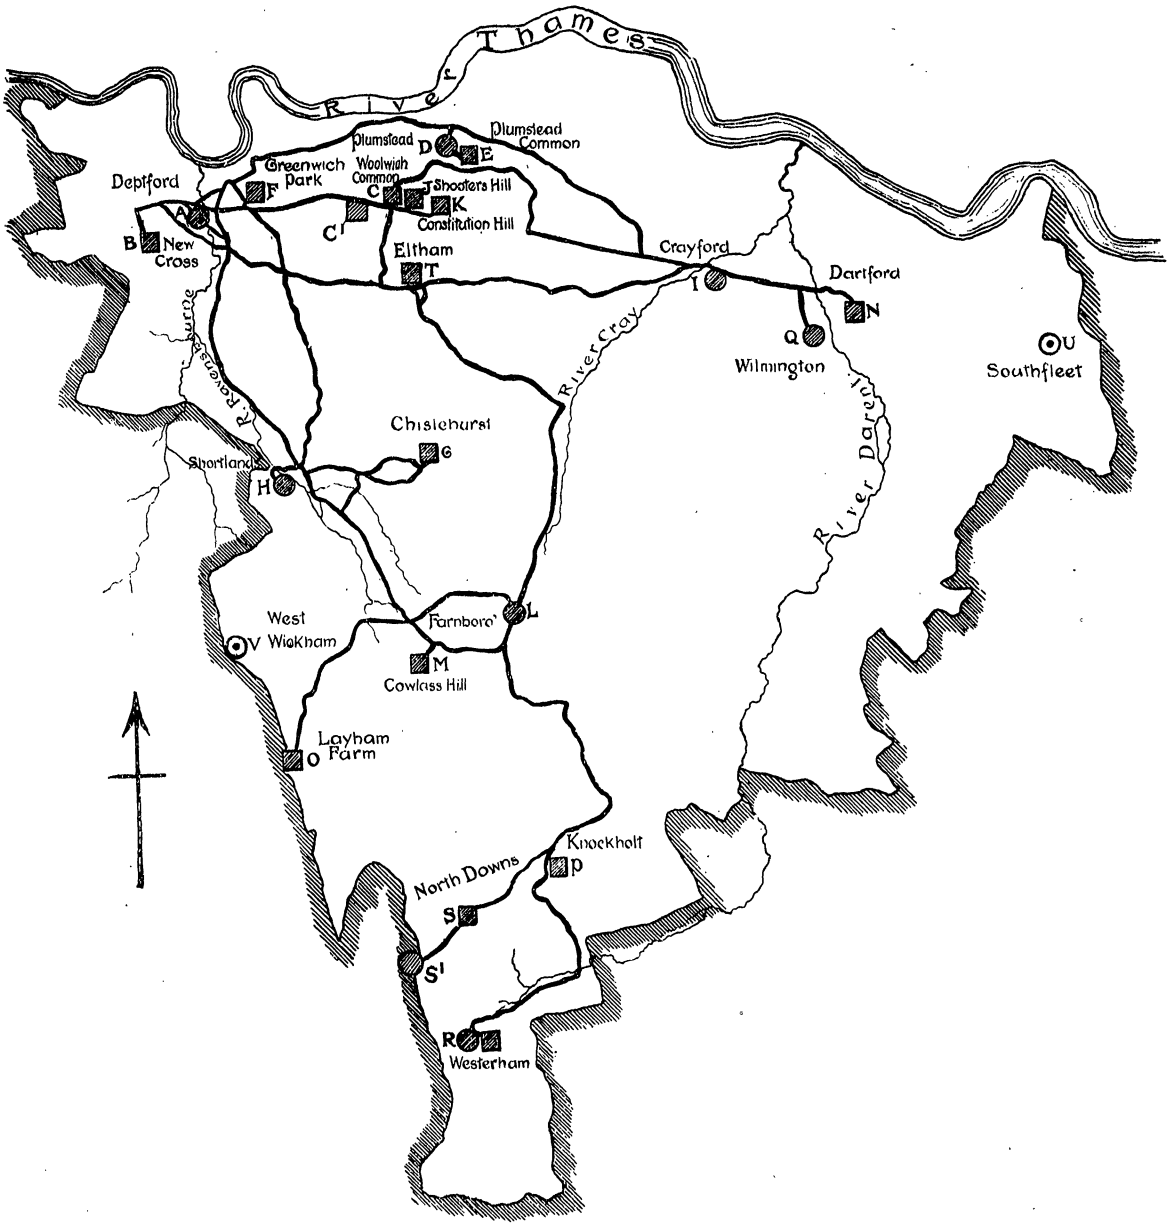
According to the report given by the secretary of the Company, the engines at Deptford have a total horse-power of 858.

New Cross (see B on Map).—The station at New Cross is situated in Jerningham-road, Hatcham, not far from the church dedicated to St. James. It consists of a reservoir, built in brick, arched over, and covered with turf. It is capable of holding 1,750,000 gallons. The top water line is 163 ft. above ordnance datum.

Woolwich Common (see C on Map).—There is a covered reservoir on Woolwich Common. It is situated to the south-west of the Royal Military College, and to the south of the road between the college and the Herbert Hospital. The part of the common which is occupied by the reservoir is enclosed by low iron railings to keep off cattle. The reservoir is of oblong form, covered by brick arches, and turfed over. It is capable of holding 1,500,000 gallons and is situated 248 ft. above ordnance datum.

Plumstead (see D on Map).—The station at Plumstead consists of a well and pumping station. The well is 136 ft. in depth and is lined by brick to a depth of 78 ft., and there is a bore-hole 600 ft. in depth. When visited on March 25th the water level was 107 ft. below the surface. After pumping the level has been as low as 112 ft. below the surface. Usually the well is pumped for from twelve to sixteen out of the twenty-four hours. The water is pumped by a rotative engine of 60 horse-power, which works a pair of lift-pumps and four force-pumps driven through tooth gearing. The steam is generated by two Cornish boilers working at a pressure of 30 lb. The amount of water pumped daily averages about 750,000 gallons. From this well Plumstead and Woolwich are supplied directly, and some of the water goes to the reservoir on Plumstead Common.

Plumstead Common (see E on Map).—The reservoir, built in the year 1854, is situated at a height of 170 ft. above ordnance datum. It is covered by brick arches which are supported by iron girders. The reservoir is divided into two parts internally. It is capable of holding 650,000 gallons. There is sufficient land here for another reservoir of the same size.



Greenwich Park (see F on Map).—This reservoir is situated at the highest part of Greenwich Park, not far from the Royal Observatory. The original reservoir was built by the Admiralty to store water to be used in case of fire at the Dockyard, the Victualling Yard, or the Greenwich Hospital (now the Royal Naval College). It was made about the year 1845, just after a destructive fire had occurred at the Tower of London. The reservoir is circular in form, and is now covered over by brick arches which are supported by iron joists. It is capable of holding about 1,125,000 gallons, and the top water-line is 158 ft. above ordnance datum. The water is used for the supply of Deptford and Greenwich. There is an electrical apparatus here connected with an index at the Deptford station which shows the height of the water in the reservoir, which it is necessary for the Company to know, because under the terms of their agreement with the Government Department a sufficient amount of water has to be constantly kept here, so that it may be available at all times in case of fire. The electrical apparatus was put up and is kept in working order by the Post Office authorities at the expense of the Company.

Chislehurst (see G on Map).—This station is situated at the upper part of Bickley Park, near Chislehurst Common. There is a reservoir, built of brick, covered with arches and turfed over. It has a capacity of 450,000 gallons, and the top water line is 315 ft. above ordnance datum. The water is supplied from Shortlands, and is distributed to the Bromley district.

Shortlands (see H on Map).—The station at Shortlands is situated 130 ft. above ordnance datum. There are here two deep wells sunk into the chalk. The wells are about 80 ft. in depth and lined with iron cylinders. From the bottom of

[1] Nos. I., II., III., IV., V., VI., and VII. were published in THE LANCET of Feb 20th and 27th, March 6th, 13th, 20th, and 27th, and April 3rd, 1897, respectively.

Hosted by Google

the wells bore-holes pass to a depth of 200 ft. The natural water level is about 10 ft. below the surface of the ground. After pumping the level has sunk to a level of 34 ft. 6 in. below the surface. The amount of water pumped averages 2,250,000 gallons daily. It is raised from the well to the ground level by two lift-pumps and forced into the mains by two piston and plunger pumps, worked by two inverted Cornish engines, for which the steam is generated by four Cornish boilers. These wells supply Chislehurst reservoir, Deptford, and Lewisham.

Crayford (see I on Map).—This station is situated 30 ft. above ordnance datum. There are three wells here. The one first made is 28 ft. in depth, the second 34 ft., and the third 48 ft. The wells are lined with iron cylinders. Each well has a bore-hole about 200 ft. in depth. Wells No. 2 and No. 3 are generally used. The water has been as low as 28 ft. below the surface in No. 2 and as low as 35 ft. below the surface in No. 3. At this station pumping is continuous, and the amount of water obtained averages 3,500,000 gallons daily. The water is raised to the surface by lift-pumps and forced into the mains by three-throw plunger-pumps, worked by two rotative beam-engines. The steam is generated by six Cornish boilers. No. 2 engine pumps to the high-level reservoir at Woolwich Common, and No. 3 to Plumstead and Woolwich. The well No. 1 is now not used. The pumping arrangements consist of a lift-pump and a direct acting force-pump, worked by a horizontal engine. The united horse-power of the three engines is 186 (nominal).

Dover-road, Shooter's Hill (see C^1 on Map).—There is a pumping station here. A pair of 24 horse-power horizontal engines work direct acting force-pumps for the supply of Shooter's Hill. Some of the water passes though a standpipe (see K on Map) situated on the summit of the hill, and of which the highest point is about 470 feet above ordnance datum. The engines are worked for about six hours a day.

Constitution Hill, Shooter's Hill (see J on Map).—There is a reservoir here, covered with brick arches, capable, theoretically, of holding 300,000 gallons, but it is not filled. It stands at a level of 320 ft. above ordnance datum. The higher parts of Plumstead and Abbey Wood are supplied from this source.

Farnborough (see L on Map).—The Farnborough station is situated 220 ft. above ordnance datum, near Orpington railway station on the South-Eastern Railway. The chalk is here about 30 ft. below the ground level. There are two deep wells about 15 ft. apart, but connected below by a gallery. The upper 30 ft. of the wells are bricked, and there are iron cylinders below this level. When visited on March 25th the water level was about 60 ft. below the surface of the ground. Occasionally in summer the water level is as low as 90 ft. below the surface. The average amount of water pumped daily is from 2,500,000 to 3,000,000 gallons. There are four engines and pumps at this station. A pair of plunger-pumps, worked by a double-cylinder Cornish engine of about 120 horse-power, pump water to Sidcup, Eltham, and Woolwich. A piston and plunger pump (No. 1), worked by a Cornish engine, pumps the water to Farnborough and Chislehurst. A small engine of the Worthington type is used for pumping to the reservoir at West Wickham and to Keston. Another small engine of the Worthington type pumps water to Knockholt reservoir. The steam for these engines is generated by six Cornish boilers, four working at a pressure of 100 lb. and the other two at 35 lb. There is an apparatus at this station for softening the water used for the boilers. A workman's cottage is situated here.

Cowlass Hill, Farnborough (see M on Map).—There is a reservoir at Cowlass Hill, near Farnborough. It is square in form, covered with brick arches, and turfed over. It is capable of holding 1,400,000 gallons. The top water level is 439 ft. above ordnance datum.

Dartford (see N on Map).—Here there is a reservoir of circular form, 60 ft. in diameter, and 20 ft. in depth. It is covered by arches of brick resting on rolled joists supported partly by a central iron column. The capacity of the reservoir is theoretically 370,000 gallons, but it is not filled. The top water level is 130 ft. above ordnance datum.

West Wickham (see O on Map).—The station to which this name is given is situated close to the high road about three miles from the village of West Wickham, on Layham Farm. There is a circular reservoir covered with brick arches and turfed over. It has a capacity of 250,000 gallons. The top water level is 550 ft. above ordnance datum. The reservoir is enclosed by an iron fence.

Knockholt (see P on Map).—The station is situated near to, but on higher ground than, the well-known Knockholt Beeches, which are a landmark for miles round. There is a reservoir, covered with brick arches and turfed over. The top water level is 795 ft. above ordnance datum. The water is pumped here from Farnborough and is used for the supply of Knockholt, Brasted, and Westerham.

Wilmington (see Q on Map).—The station at Wilmington is situated at the extreme northern extremity of that parish, about a mile south of the town of Dartford, near the Dartford powder-mills, in the valley of the Darenth, and not far from the river. Two wells, pumping apparatus, and workmen's cottages are situated here. The wells are about 100 ft. in depth, lined with iron cylinders, and bricked at the upper part. One of the wells (No. 1) has a short gallery in the chalk. The other (No. 2) has a longer gallery ending in a bore-hole about 200 ft. in depth. The water level varies from 40 ft. to 80 ft. below the ground level, which is 30 ft. above ordnance datum. The amount of water pumped daily varies from 3,000,000 to 6,000,000 gallons. The water is pumped by a pair of compound rotative beam-engines of 260 horse-power, which work two lift-pumps for raising the water from the wells, and two pairs of force-pumps which send the water through a 24 in. main to Eltham reservoir.

Westerham (see R on Map).—The Westerham station is situated on the outskirts of the Equerry's Park. It consists of a well 70 ft. in depth, pumping arrangements, and a reservoir. The water is pumped by an overshot water-wheel, and the stream which turns it has a fall of about 15 feet. The amount of water pumped daily is about 25,000 gallons. It is pumped to a reservoir situated on an eminence hard by, at a height of 444 ft. above ordnance datum. The reservoir is a covered one, and is capable of holding 60,000 gallons. The village of Westerham is supplied partly from this source and partly from Knockholt.

Betsom's Hill (see S on Map).—This hill forms part of the North Downs, and on the map the station is marked too far to the east. It is nearer the boundary. There is here a covered reservoir, built of concrete, capable of holding 68,000 gallons. The top water line is 818 ft. above ordnance datum. The reservoir supplies a few houses on the hill. The water is pumped as occasion requires by a portable engine from a well (see S^1 on Map) situated at the foot of the downs, close to the Pilgrim's Way and the boundary between the counties of Kent and Surrey.

Eltham (see T on Map).—The station at Eltham is situated at the eastern end of the village of that name, at a height of 240 ft. above ordnance datum. There is a circular reservoir, covered with brick arches, capable of holding 3,000,000 gallons. The internal arrangements of the reservoir insure a circulation of the water, which comes in at the outer circle and makes three circuits before it passes out at the centre. All the water is pumped into and passes out of the reservoir every day. The property here is about three acres in extent and there is room for another reservoir of the same size. There is a garden enclosed, on three sides by a high brick wall. There is also a small house between the reservoir and the road.

Communications with other companies' mains.—There is no communication with the mains of any other company.

Length of new pipes.—The length of new pipes ranging from 3 in. to 20 in. laid in 1895 was 10½ miles, and during the year 1896 was 15⅛ miles.

Hydrants.—The number of hydrants erected during the year 1895 was 274, and during the year 1896 it was 613.

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 61,312; on Dec. 31st, 1895, 66,750; and on Dec. 31st, 1896, 71,463.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 85.

Average daily supply per head.—The average daily supply per head for the year 1896 was 32·17 gallons. These figures are arrived at by the Company as follows: Average daily supply, 16,069,991; average population, 500,286. The difference between the figures given by the Company and those given by the water examiner appointed by the Local Government Board is caused by the fact that whereas the secretary to the Company makes no allowance for "slip quantities in the pumps," an allowance for this is made by the water examiner to the Local Government Board.

Date of maximum and minimum supply.—The following

Hosted by Google

table gives the date of the maximum and minimum supplies and the average daily quantities supplied :—

—	Year 1895. Month.	Year 1895. Quantity in gallons.	Year 1896. Month.	Year 1896. Quantity in gallons.
Maximum ...	June	19,875,709	July	19,392,072
Minimum ...	December	15,156,144	November	14,621,294

Communication between the Company's stations.—With the exception of the electric communication between the Greenwich reservoir and the Deptford station there is no direct communication between the Company's various stations.

Area of Supply.

The Act of 1809 authorises the Kent Waterworks Company to supply the following places, some of which are entirely supplied and some partly supplied.

Supplied: Deptford (St. Nicholas), Deptford (St. Paul), Greenwich (St. Alphege), Lee, and New Cross (within the manor of Hatcham),

Partly supplied: Rotherhithe and Lewisham.

The Act of 1811 authorises the Company to supply the following places, of which some are entirely supplied, one is supplied in part, and some are not supplied at all.

Supplied: Charlton, Plumstead, and Woolwich (south of the Thames).

Partly supplied: Peckham.

Not supplied: Bermondsey and Peckham Rye.

The Act of 1864 authorises the Company to supply the following places, which are entirely supplied: Bexley, Bromley, Chislehurst, Crayford, Dartford, Eltham, Erith, and Wickham.

The Act of 1877 authorises the supply of the following places which are entirely supplied: Beckenham (part of), Chelsfield, Foots Cray, North Cray, St. Mary Cray, St. Paul's Cray, Darenth, Eynsford, Farnborough, Farningham, Hayes, Keston, Orpington, Stone, Sutton-at-Hone, Swanscombe, West Wickham, and Wilmington.

The Act of 1888 authorises the supply of the following places some of which are entirely supplied, one is partially supplied, and some are not supplied at all.

Supplied: Cudham, Downe, Halstead, Horton Kirby, Knockholt, Southfleet, and Westerham.

Partly supplied: Brasted, Chevening, Shoreham, and Sundridge.

Not supplied: Lullingstaine or Lullingstone (private residence), and Sundridge (part of).

Subject to request by the Sevenoaks Rural Sanitary Authority: Brasted (part of), Chevening, Otford, Shoreham, and Sundridge.

New Works in Progress.

New wells are being sunk at Southfleet, near Gravesend (see U on Map), and at West Wickham, in the valley about half a mile from West Wickham Court (see V on Map). An engine house has already been erected here.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on April 8th, the President, Sir WILLIAM MACCORMAC, being in the chair.

Mr. William Johnson Walsham and Mr. William Henry Bennett were introduced, and made declarations in the terms of the oath prescribed by the Charter of 1800 on their admission as members of the Court of Examiners.

The report of the Jacksonian Committee was received, and in accordance with its recommendation the Jacksonian Prize was adjudged to Mr. Cozens Bailey, F.R.C.S. Eng., the author of the dissertation bearing the motto, "There's the respect that makes calamity of so long life."—*Hamlet*, Act III., Sc. 1. The subject of the dissertation was "The Pathology, Diagnosis, and Treatment of Diseases of the Prostate Gland."

The selection of a subject for the Jacksonian Prize for 1898 was postponed.

The prize founded by the dental profession in honour of the late Sir John Tomes, F.R.S., was awarded to Mr. Charles Sissmore Tomes, F.R.S., Member and Licentiate in Dental Surgery of the Royal College of Surgeons of England, for his original and other scientific work in relation to dental surgery, dental anatomy, and histology.

The following report from the Committee of Management was received and adopted :—

The Committee of Management beg to make the following recommendations :—

1. That the following institutions be added to the list of recognised places of instruction in chemistry, physics, practical chemistry, and biology :—
   a. Bournemouth School of Science and Art (without biology).
   b. Bradford Technical College.
   c. Brighton Municipal School of Science and Art.
   d. Gloucester Municipal Schools of Science, Art, and Technology (without biology).
   e. Kingswood School, Bath.
2. That the courses of laboratory instruction in public health at the following medical schools be recognised as fulfilling the requirements of the regulations for the diploma in public health—viz. :
   St. Thomas's Hospital Medical School.
   Owens College, Manchester.
3. The Committee beg to report that in accordance with the request of the Royal Colleges they have considered the recommendations of the General Medical Council.

"That in regard to the midwifery practice to be required of candidates for licences to practise, it is desirable that the alternative to three months' attendance on the in-door practice of a lying-in hospital be in future defined as follows :—

"'Or to have been present at not less than twenty labours, at least five of which shall have been conducted throughout under the direct supervision of a registered practitioner.'"

The Committee have made inquiries of the teachers of the medical schools, both metropolitan and provincial, and have obtained from them their views on the recommendation of the General Medical Council in regard to practical midwifery. It appears that though in a certain number of schools the teachers are of opinion that the suggested alteration in the certificate is desirable and can be carried out satisfactorily, in others the teachers consider that the proposed attendance can only be fulfilled in a perfunctory manner; and in a majority of the schools the teachers are of opinion that it would be impracticable to carry out the proposed arrangements.

The Committee report that it is not desirable to adopt the alteration in the regulations suggested by the General Medical Council, and they recommend that a reply to this effect be sent to the Registrar of the General Medical Council.

The following report from the Laboratories Committee was received and adopted :—

1. *The work on Diphtheria for the Metropolitan Asylums Board.*

The Preparation of Antitoxic Serum.

Since December 4th the Director has supplied 3001 doses of antitoxic serum containing 4000 units each, 125 doses containing 3000 units each, 350 doses containing 2000 units each, 300 doses containing 1500 units each, and 499 doses containing 1000 units, for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, and all the demands have been fully met. During this period 14,028,000 units have been supplied, against 10,074,000 units last quarter, being an increase of 3,954,000 units.

2. *Researches in connexion with the Grant from the Goldsmiths Company.*

The Director has made the following report on the recent work done under the Goldsmiths' Research Grant, viz. :—

Since my last report on the work done in connexion with the Honourable Goldsmiths' Company Grant, Dr. Wood has continued his investigations on the production of potent diphtheria antitoxins, and has succeeded by his new method (already reported) in obtaining large quantities of strong antitoxic serums.

The highest of these serums (800 units per c.c.) is much more potent than any that has yet been placed on the market, even in Germany, where the only one that approaches it in strength is that manufactured by Professor Behring, which contains 600 normal units per c.c.

The strongest of these serums prepared by Dr. Wood has been supplied to Dr. Sidney Martin at University College Hospital, who reported to THE LANCET, Oct. 17th, 1896, that he had obtained most remarkable results by its use. In 1894 the percentage death-rate from diphtheria in that hospital was 39. In 1895, the first year in which antitoxin was used, the death-rate had fallen to 28, and in 1896 (Sept. 22nd), when the strong serum was used, to 20·5.

In Dr. Martin's figures we have additional evidence of the importance of the treatment of diphtheria by antitoxin serum at as early a stage of the disease as possible.

Dr. Martin also notes that the number of cases of post-diphtheritic paralysis was very small—only three in the whole of the cases that recovered—that not a single case of abscess occurred, and that rashes on the skin and pains in the joints were of very rare occurrence.

He further notes that no cases proved fatal unless they were severe on admission, and states that the more potent the serum the better will be the results obtained by its use, both as regards immediate effect and as preventing injurious after effects.

Dr. T. G. Brodie continues his investigations on the separation of antitoxin from the serum in which it is contained, but as yet has nothing further to report.

Whilst these investigations have been in progress I have consulted with the various workers, and have inspected and controlled many of the experiments, especially those connected with the determination of the strength of the antitoxin produced. Along with Dr. Wood I have made a large series of experiments on the standardising of test toxin

Hosted by Google

and antitoxin, which, however, are not as yet completed. In addition I have, with the help of the laboratory staff and the gentlemen above mentioned, been able to make numerous improvements in the methods of injecting the horses, of collecting blood, and separating the active serum; of keeping it aseptic; of clearing it by sedimentation; of storing it in bulk, and of decanting and distributing it in convenient form for use. Concerning these and other improvements in methods and detail I hope to give a fuller report at a future date. I cannot speak too highly of the fashion in which the investigators under the grant have carried out the work assigned to them.

In fulfilment of one of the conditions of the grant from the Goldsmiths' Company, that antitoxin should be, if possible, supplied for use amongst the poorer classes of the community, antitoxic serum has been supplied to various general and children's hospitals in London during the past quarter, as well as to certain medical practitioners for cases fulfilling the necessary conditions.

The Laboratories Committee have made a grant of £100 to the Director for his valuable services in connexion with these researches.

A statement of the attendance at the lectures delivered at the College was presented, from which it was seen that the average number of persons attending at each lecture was slightly over thirty.

The President stated on behalf of himself and the vice-presidents that they considered it desirable that an address of congratulation should be presented by the College on the occasion of the sixtieth anniversary of Her Majesty's accession, but that no further steps should be taken to celebrate the event.

A letter was read from the British Institute of Preventive Medicine offering to the Council the opportunity of nominating a representative on the Council of the Institute in the vacancy caused by the death of Sir Spencer Wells. It was agreed that the President for the time being should act as the representative.

The President (Sir William MacCormac) and Mr. T. R. Jessop were appointed delegates to the Twelfth International Congress at Moscow.

In reply to a letter from the Earl of Stamford, requesting each member of the Civil Rights Defence Committee to contribute £15 in order to discharge the liabilities of the Committee, amounting to £150, it was agreed to say that the Council could not make any contribution out of the College funds.

The Honorary Medal of the College was awarded to Sir James Paget and to Lord Lister.

Mr. William Appleton Meredith was elected a Fellow of the College under the section relating to the election of Members of twenty years' standing.

The consideration of Mr. W. Rivington's proposal to appoint a committee to inquire into the origin and meaning of By-law XV. was postponed.

BUBONIC PLAGUE IN INDIA.

THE accounts in the Anglo-Indian papers received by the last mail are more satisfactory. They show that the diminution that has taken place in the prevalence of the disease is being maintained. The latest telegram from the Governor of Bombay to the Secretary of State for India contains, however, news of a later date than that furnished by the Indian press, which only extends to the 27th ult., whereas the telegram furnishes intelligence up to the week ending the 9th inst. The deaths from all causes up to that date in Bombay city were 983, and the reported deaths from plague 368. We learn from the Indian papers that the Plague Committees are working very energetically, and the work of house-to-house visitation has resulted in the discovery of many concealed cases. The health of the city is reported as having improved during the week ending March 27th last, the total mortality, although still 600 above the average for the corresponding period during the preceding five years, was 119 less, and the deaths from plague 5 less, than that of the past week. His Excellency the Governor of Bombay had recently accompanied the committee in a tour of inspection of the isolation hospitals provided for the sufferers from the disease. The Mohammedan population recently presented a petition praying to be exempted from the segregation regulations, but the Governor very wisely, in the interest of public health, refused to accede to their request. The natives of India are naturally a very patient and law-abiding people, and notwithstanding the strength of their caste prejudices and traditions they like to have a Government which really governs, if they are only convinced of its honesty, justice, and impartiality. There have, of course, been some riots and manifestations of resistance to the new order of things. This was only to have been anticipated. But the way in which the natives have yielded to the orders of Government in connexion with the efforts that are being made to control the spread of the disease has been a remarkable and, on the whole, gratifying feature in the history of the epidemic. We trust that the application of the powers conferred by the Epidemic Diseases Act will be limited to plague cases, and that the natives will be relieved of all expense attending the cleansing and disinfection of their houses. We have already apprised our readers of the telegraphic intelligence received by THE LANCET, that the results of Dr. Yersin's antitoxic serum treatment had, unhappily, not been so successful as was anticipated, and that it was, in fact, regarded as having failed. M. Haffkine's work has appreciably increased. A laboratory has been fitted up for him on the Malabar Hill ridge. Requisitions are being received from all parts of the Presidency for the supply of his prophylactic serum, and he has been compelled to discontinue his inoculation work in order to devote himself to the preparation of serum, prophylactic and curative, to meet the demands. The number of persons that have been inoculated since Jan. 1st to March 22nd, the *Times of India* tells us, is 3452, of whom 376 are Europeans, 1632 Parsees, 174 Brahmins, 848 Hindoos, 242 native Christians, 159 Mohammedans, and 20 Jews. Amongst the inoculated are the Bishop of Bombay, the Hon. Mr. Nugent, Member of Council, judges of the High Court, several officials, and notable citizens. Tested by the method observed in the Pasteur Institute at Paris the result of the prophylactic treatment has proved to be productive of good.

The plague still continues at Karachi, and, according to the news received by the last mail, shows no signs of abatement. The total number returned from the beginning of the outbreak to March 26th is 2919 cases and 2470 deaths. At Poona there have been altogether 869 cases and 654 deaths.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6550 births and 3917 deaths were registered during the week ending April 10th. The annual rate of mortality in these towns, which had been 18·7 and 18·3 per 1000 in the two preceding weeks, rose again last week to 18·6. In London the rate was 17·5 per 1000, while it averaged 19·3 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·2 in Brighton, 12·6 in West Ham, 13 5 in Swansea, and 14·2 in Halifax; the highest rates were 23·1 in Liverpool, 26·2 in Bolton and in Huddersfield, 26 7 in Manchester, and 27·1 in Salford. The 3917 deaths in these towns included 338 which were referred to the principal zymotic diseases, against 359 and 344 in the two preceding weeks; of these, 106 resulted from whooping-cough, 88 from measles, 46 from diarrhœa, 43 from diphtheria, 31 from scarlet fever, and 24 from "fever" (principally enteric). No death from any of these diseases was recorded last week in Croydon, Swansea, Derby, or Halifax; in the other towns they caused the lowest death-rates in Leeds, Bradford, and Norwich, and the highest rates in Oldham, Gateshead, Bolton, and Salford. The greatest mortality from measles occurred in Gateshead, Newcastle-upon-Tyne, Manchester, Burnley, Salford, and Bolton; and from whooping-cough in Salford, Huddersfield, Bristol, and Gateshead. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 43 deaths from diphtheria included 23 in London, 5 in Cardiff, 3 in West Ham, 2 in Oldham, and 2 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 16 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, April 10th, against 29, 21, and 17 at the end of the three preceding weeks; one new case was admitted during the week, against 2·2 and 0 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital at the end of the week was 2449, against 2622, 2585, and 2512 on the three preceding Saturdays; 224 new cases were admitted during

Hosted by Google

the week, against 206, 224, and 219 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 313 and 282 in the two preceding weeks, further declined last week to 271, and were 121 below the corrected average. The causes of 47, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Oldham, Sunderland, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 23·3 to 22·1 per 1000, rose again to 24·6 during the week ending April 10th, and was as much as 6·0 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 19·5 in Leith up to as much as 25·8 in Dundee and 26·7 in Edinburgh. The 733 deaths in these towns included 38 which were referred to whooping-cough, 33 to measles, 14 to diarrhœa, 4 to diphtheria, 3 to scarlet fever, and 3 to "fever." In all, 95 deaths resulted from these principal zymotic diseases, against 96 and 104 in the two preceding weeks. These 95 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 1·5 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 33 and 41 in the two preceding weeks, declined to 38 last week, and included 26 in Glasgow and 6 in Edinburgh. The deaths referred to measles, which had been 36 and 29 in the two preceding weeks, rose again to 33 last week, of which 21 occurred in Edinburgh and 10 in Glasgow. The 4 fatal cases of diphtheria showed a decline of 5 from the number recorded in the preceding week, and included 2 in Glasgow and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 6 in the two preceding weeks, declined again to 3 last week. The deaths from diseases of the respiratory organs in these towns, which had been 159 and 146 in the two preceding weeks, rose again to 153 last week, but exceeded by 66 the number in the corresponding period of last year. The causes of 38, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 36·1 and 38·5 per 1000 in the two preceding weeks, declined again to 35·9 during the week ending April 10th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 40·2 per 1000, the rate during the same period being 18·4 in London and 22·4 in Edinburgh. The 241 deaths registered in Dublin during the week under notice showed a decline of 17 from the number in the preceding week, and included 41 which were referred to the principal zymotic diseases, against numbers declining from 74 to 47 in the two preceding weeks; of these, 25 resulted from measles, 9 from whooping-cough, 3 from scarlet fever, 2 from diphtheria, 1 from "fever," and 1 from diarrhœa. These 41 deaths were equal to an annual rate of 6·1 per 1000, the zymotic death-rate during the same period being 1·5 in London and 5·5 in Edinburgh. The fatal cases of measles, which had been 46, 37, and 27 in the three preceding weeks, further declined to 25 last week. The deaths referred to whooping-cough, which had declined from 20 to 9 in the three preceding weeks, were again 9 last week. The 3 fatal cases of scarlet fever were within one of the number recorded in the preceding week. The 241 deaths in Dublin last week included 43 of infants under one year of age and 43 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the number recorded in the preceding week. Seven inquest cases and 7 deaths from violence were registered; and 71, or nearly a third, of the deaths occurred in public institutions. The causes of 21, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN W. B. LEISHMAN, having reported himself at the Royal Victoria Hospital, Netley, is taken on the strength and posted to the Surgical Division for duty. Surgeon-Major Crofts and Surgeon-Lieutenant Stammers proceed to Cork for duty, and Surgeon-Lieutenant Clarke has been posted to Dublin. Surgeon-Colonel Townsend has embarked for Bombay, and Surgeon-Major Lyle has been appointed to the charge of the Station Hospital at Colaba. Surgeon-Major North has joined at Woolwich for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel J. McCloghry and Surgeon-Major W. H. Burke have respectively delivered over and received charge of the Rajkot Prison. The services of Surgeon-Lieutenant C. Thomson (Bengal) are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Fleet Surgeons: Anthony Gorham to the *President;* and Michael Fitzgerald to the *Majestic.* Staff Surgeon Henry E. South to the *Intrepid.* Surgeons: John Lowney to the *Melampus,* and Herbert P. Shuttleworth to Chatham Hospital.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain William Lloyd Edwards, Severn Division, Submarine Miners, Royal Engineers (Volunteers), to be Surgeon-Captain. The under-mentioned officers to be Surgeon-Lieutenants: Surgeon-Lieutenant Harry Legh de Legh, 1st Volunteer Battalion the Princess of Wales's Own (Yorkshire Regiment), and Surgeon-Lieutenant William A. Griffiths, 1st Volunteer Battalion the Hampshire Regiment.

VOLUNTEER CORPS.

Royal Engineers (Volunteers): 1st Hampshire: Surgeon-Lieutenant William Blaikie Mason resigns his commission, and is appointed Second Lieutenant. *Rifle:* 3rd Volunteer Battalion the Lancashire Fusiliers: Surgeon-Lieutenant S. McNair resigns his commission. 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Surgeon-Captain C. Knott to be Surgeon-Major.

RATES OF PAY FOR THE MEDICAL SERVICES IN INDIA.

The Secretary of State for India has approved the following revised rates of pay for officers of the Army Medical Staff borne on the Indian establishment and for certain grades of the Indian Medical Service, with effect from April 1st, 1897: Brigade-surgeon-lieutenant-colonel, Rs. 1150 per mensem; surgeon-lieutenant-colonel, Rs. 1056—after twenty-five years' service, Rs. 1093; surgeon-major, on appointment, Rs. 789—after fifteen years' service, Rs. 825; surgeon-captain and surgeon-lieutenant, Rs. 350; surgeon-captain after five years' service, Rs. 450; surgeon-captain after ten years' service, Rs. 500. These rates of pay, however, will not be applicable to officers of the Indian Medical Service holding no specific appointments, except surgeon-captains and surgeon-lieutenants. The grade pay laid down in Article 306 C, Army Regulations, India, Volume I., for officers of the Indian Medical Services is to be revised as follows: Brigade-surgeon-lieutenant-colonel, Rs. 900; surgeon-lieutenant-colonel, Rs. 852—after twenty-five years' service, Rs. 888; surgeon-major, on appointment, Rs. 640—after fifteen years' service, Rs. 677; surgeon-captain and surgeon-lieutenant, Rs. 300; surgeon-captain after five years' service, Rs. 400; surgeon-captain after ten years' service, Rs. 450. These rates of pay will be drawn by all medical officers in receipt of staff salary or holding no specific appointments, except as provided in Article 520 of the Regulations quoted. A brigade-surgeon-lieutenant-colonel in charge of a native regiment is to receive Rs. 1100 per mensem, consolidated pay.

THE "DRUMMOND CASTLE" AND "WARREN HASTINGS" DISASTERS.

The extremely kind and sympathetic way in which the French have behaved to the passengers and crews in connexion with both these wrecks has been most gratifying. Of course, the scene of the disaster was different in the two cases, but the treatment accorded to the sufferers was the same. It will be remembered that in the case of the

Hosted by Google

Warren Hastings the troops on board that vessel, who behaved with so much courage, coolness, and perfect discipline under the most trying circumstances, met with great kindness and assistance from the French authorities and inhabitants. The circumstances of the *Drummond Castle* disaster are still fresh in the recollection of most people. We are glad to notice that a clock for the church tower of Molène has recently been presented, in commemoration of their charitable and friendly conduct to the curé and the rest of the French population of that place. The medals struck by order of Her Majesty to mark the memorable services of the fisher-folk at the time of the loss of the *Drummond Castle* will be presented by Sir E. Monson, the British Ambassador, on the 27th inst.

THE TURKO-GREEK FRONTIER FORCES.

No information has been published regarding the health of the Greek force. There has been a heavy fall of snow in the vicinity of Trikhala, and some of the Italian volunteers who took part in the late invasion of the Turkish frontier have been unable to endure the cold and have returned. The Turkish army is said to be healthy and fairly well provided. The number of their sick in the four divisions posted in the neighbourhood of Elassona only amounts, it is reported, to 1 per cent. Edhem Pasha has authorised the *Times* special correspondent to contradict the rumour as to the prevalence of small-pox in his force; there is not a single case in the whole army.

The Queen has granted the under-mentioned officers Her Royal licence and authority to wear the Insignia of the Imperial Order of the Medjidieh of the Fourth Class, which has been conferred upon them in recognition of active and distinguished service before the enemy during the recent Dongola Expedition: — Surgeon-Captain Charles Stuart Spong, A.M.S., and Surgeon-Captain Henry Ernest Hill Smith, A.M.S.

Correspondence.

"Audi alteram partem."

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of to-day Professor G. V. Poore remarks—"I believe that right-handedness is a necessity and depends upon the distribution of the weight of the viscera in the thorax, and that our four-limbed ancestors were right-pawed long before they began to stand on their hind-legs for oratorical or other purposes. The weight of the viscera in the left half of the thorax is considerably greater than that of those in the right half." That is so, but it is mainly in the abdomen the disturbance of equipoise arises, the liver more than balancing the cardiac preponderance on the left side, and placing the centre of gravity to the right side. For the demonstration of that, reference may be made to the evidence contained in my paper "On the Relative Weight of the Viscera on the Two Sides of the Body; and on the consequent position of the Centre of Gravity to the Right Side."[1] From experiments made in the dissecting room and post-mortem room, extending over several years, the conclusion reached was that the viscera give a preponderance to the right side of 22¾ oz.; or, if deduction be made for the weight of food in the stomach, of 15 oz. clear preponderance on the right side, in the adult. And that is not an over-estimate. We have thus a natural physical cause. The greater weight on the right side leads to resting most on the right leg, and, from this pillar of support, we naturally use the right upper limb preferentially.

The question is—Why the hand of that side is the preferred one among all races of mankind? In view of the close correspondence in internal structure among all races of mankind, it is not easy for the anatomist to believe that the human species arose otherwise than from one centre. That may be held although the phenomena of development, the presence of rudimentary structures, and the occurrence of minor variations point to the descent of man from some previous form. On the hypothesis of unity of origin the explanation of right-handedness is easy. One hand would naturally be fixed on; the young would be trained to use the same hand; and the influence of that on the left hemisphere of the brain would ere long give a hereditary or "instinctive" tendency to prefer the right hand. But from the beginning there has been the natural physical cause in visceral preponderance on the right side, and whatever hypothesis we adopt as to the origin of man, that cause has been in operation as a potent accompaniment of the erect posture.

The late Professor Andrew Buchanan of Glasgow had, in 1862, propounded the hypothesis of the above-mentioned physical cause, founding it on the idea that by the descent of the diaphragm in inspiration the liver is pushed to the right side, disturbing the supposed equipoise. My research, above referred to, gave his hypothesis a basis in anatomical fact, that there is naturally a considerable visceral preponderance on the right side, and the mode of operation of that physical cause is evident. To that passive physical cause would soon come to be added the effect of the greater use of the right hand on the activity of the left cerebral hemisphere; thus bringing heredity to strengthen the tendency to prefer the right hand, originating in the visceral preponderance. Thus, the greater activity, or it may be also the greater bulk, of the left hemisphere of the brain is not the primary cause, but merely the secondary or ancillary cause.

The whole question is ably discussed by my late esteemed friend, Sir Daniel Wilson,[2] but it will not do, as he concludes, to put aside the hypothesis of the influence of visceral preponderance from the difficulty of its not fitting every exceptional case. For example, cases of transposition of the viscera in which the person was not left-handed. We do not know what the early domestic training of these persons was, and it does not follow that the hereditary transmission to the left brain had also been transposed. No explanation that I have yet seen propounded can account satisfactorily for the occasional occurrence of instinctive and inveterate tendency to left-handedness, of which Sir Daniel Wilson himself was an example. The supposition of variation in the direction of the heredity, going to the right hemisphere instead of the left, might, however, be a satisfactory explanation. There is no accounting for some of Nature's variations. Why not the occurrence of transposition of heredity between the two sides of a bilateral organ *per se*, as well as the occurrence of transposition of unilateral organs *per se*? We can give no reasonable explanation of the latter occurrence.

The preferential use of the right hand does not, according to my observation, show itself in very young children, but only after they have assumed the erect posture and begun active exertion. Nor does it follow that the part heredity plays will operate from the very beginning. Heredities have their period in showing themselves. The visceral preponderance hypothesis applies to a much less degree in the quadruped, but leather merchants tell us that the right side of the hide is known as the "lying" side. The want of equipoise tells more in the human form, owing to the erect posture and the greater lateral development of the trunk; and the less intelligence of the quadruped dispenses with the advantage of a skilled limb. In regard to the use of our feet, relatively there is not much difference, but we use the right preferentially in vigorous acts. The right lower limb has become the stronger from being the chief pillar of support under visceral preponderance, and the reaction of the consequent greater development of the left cerebral hemisphere will come to contribute. I think most persons, who have never had an injury to either lower limb, will find that the sole of the right shoe wears before that of the left.

I am, Sirs, yours faithfully,

Edinburgh, April 10th, 1897. J. STRUTHERS.

"THE HOSPITAL REFORM ASSOCIATION: REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON."

To the Editors of THE LANCET.

SIRS,—Permit me, as a hospital secretary with an experience in both general and special hospitals of close upon a quarter of a century, to make brief comment on the "Report of the Committee appointed to Inquire into the

Hosted by Google

Working of the Special Hospitals of London." Presuming to take my own case as a sample of the rest, I fully reciprocate the general acknowledgment of the committee for courteous reception, but I must add from the manner in which they exercised their commission, as well as from the very nature of a tabular statement, no new facts are really brought forward. Those that are presented we have been quite familiar with, for similar statements have been published times without number during the past twenty-five years. But the report now under consideration clearly shows that the imputation so freely laid against special institutions, that "hospital abuse" is more rampant with them than with the older and larger hospitals, is practically dispelled.

To state my objections, still briefly, but with more detail. In the first place the visit, which should have been one of hours in duration, was, at this hospital at least, hardly of minutes, and this in spite of my eagerness for thorough investigation. In fact, an excuse for hurry both commenced and cut short the interview. So anxious, however, was I that the report should be full and complete that I called on one of the members of the committee. As a result I was asked to add in writing to their report; but since this addition—to be presently alluded to—is not published it might as well not have been made. Secondly, a tabular statement, always incomplete, is in this instance especially unsatisfactory, since it implies an effort to bring into harmony things which are dissimilar—e.g., an ophthalmic hospital, treating probably a hundred new out-patients each day, is compared with a hospital for paralysis, which admits from two to three only. Thus, although £318 is taken in boxes from the former, the proportion of self-help on the part of the patient is nothing when compared with that of £632 from the Paralysis Hospital, where, with an average of from two to three per diem, one-half are stated to have a letter and the remainder are reported to pay only 6*d*. Without pointing to other discrepancies, the appended "remarks" are both incomplete and incongruous—incomplete, for instance, because I stated, in answer to an invitation, that in the past year 1000 patients had been sent by medical practitioners, and "that the majority of these patients sent by medical men are in a much better position of life than the patients not so recommended, and that the patients are not merely sent for a diagnosis, but for the treatment." These words have been omitted. Indeed, so frequent is the charge that general practitioners are injured by these special hospitals that it is a matter of surprise the committee did not ask for information on this point. Had they done so my experience leads me to believe that this imputation would have been dispelled as completely as many other equally baseless in fact. To give but one instance of the incongruity of the "remarks" of the committee, they have included two or three institutions which are apparently private concerns, and another one which is in no sense a hospital, but a home for the dying. Finally, it must be gratifying to all concerned with special hospitals that there is no evidence deduced that the medical officers of the institutions derive personal emolument as has been so frequently asserted; and, indeed, the suggestion of the committee that patients "might obtain a specialist's advice on the payment of a small sum, say, from 5*s*. to 10*s*., a portion of which would go to the specialist himself," would be generally dismissed with scorn. The committee, however, be might have gone further; the information supplied shows that an institution may be conducted on a charitable basis yet with businesslike principles, and, indeed, if these were more generally recognised the whole question of hospital impecuniosity might be solved—but that is another story.

I am, Sirs, your obedient servant,

RICHARD KERSHAW,
Secretary, Central London Throat and Ear Hospital.
Gray's-inn-road, April 12th, 1897.

HOSPITAL ABUSE AND ITS SUCCESSFUL PREVENTION.

To the Editors of THE LANCET.

SIRS,—During the last six years a scheme for the prevention of abuse in the out-patient department has been in force at the Great Northern Central Hospital at Holloway, and the success that has attended it will be of interest to hospital managers and others who have paid attention to this vexed question. The Great Northern Central Hospital scheme consists essentially of systematic inquiry both as to the social and as to the medical fitness of its applicants for relief. The social qualifications are investigated by a sub-committee composed of representatives of the committee of management and the medical staff. Their inquiry officer, who must be well acquainted with the district and with the conditions of labour therein, is required by them to investigate every case, and if any doubt arises in his mind as to the social fitness of any patient for gratuitous relief he is empowered to put a series of questions laid down by the sub-committee and to record the answers on special forms. These questions relate to wages and income from all sources, number of children, duration of illness, whether in or out of work, &c. The answers are then compared with a wages scale, carefully drawn up to meet all ordinary cases, and approved by the local managers of the Hospital Saturday Fund. If the case does not come within the limits of the scale the patient is refused further aid unless he provides himself at his next visit with a certificate of fitness from his own medical man or his employer, a blank form being given to him for the purpose. First aid is, however, given in nearly all cases. The medical fitness of applicants is decided by a special medical officer, also a resident in the district, who only admits patients to the out-patient department suffering from definite illness. He is empowered to treat the trivial cases once, but such patients are not permitted to attend a second time.

In October, 1891, after the system had been in force for twelve months, the sub-committee were able to report "that cases of flagrant abuse of the charity have been promptly detected and summarily excluded, and that more than half the number of those required to bring certificates failed to bring them." A second inquiry into the working of the system from 1892 to 1896 has recently been made, and it has been shown that flagrant abuse is now rarely attempted. For instance, in the year 1895 the total number of new patients was 18,050, of whom only 423 were excluded. In the year 1896 the number of patients had risen to 20,935, and the cases excluded by the system of inquiry fell to 200. Taking the figures for both years it is shown that the number of actual rejections has been as few as 1·6 per cent. The figures show that the number of applications has increased, and it is thus evident that the system has only driven away the unsuitable applicants for relief, while it remains popular with the really necessitous poor. It is worthy of note that in one year 68 per cent. of the certificates returned were signed by the patients' own medical men. It may be assumed that many of the patients who have been refused as unsuitable at the Great Northern Central Hospital have applied successfully at some other hospital where no questions are asked, and it is obvious that the abuse of the charities by such people can only be checked by the adoption of a uniform system of inquiry. We consider, however, that the experience of our hospital has clearly shown that it is possible to protect the great medical charities from abuse without any injustice towards rightful applicants for relief.

We are, Sirs, yours faithfully,

C. T. MURDOCH, Chairman,
W. BURDETT-COUTTS, Treasurer, } Great Northern Central Hospital.

March 31st, 1897.

To the Editors of THE LANCET.

SIRS,—I wish to bring this paragraph in the *City Press* to your notice as we have been told that special hospitals are particular offenders against the medical profession in the matter of indiscriminate out-patients:—

"So much is constantly heard of the laxity that prevails at our hospitals as regards the admission of patients who are able to pay for medical attendance that it may not be inopportune, more especially in view of the Prince's appeal, to give a glimpse of the other side of the picture. Such a view is afforded by a statement made in the annual report of the Royal London Ophthalmic Hospital. It seems that last year no fewer than 823 persons were rejected on the ground that, on investigation, it was found that their cases were not such as to entitle them to relief. This total represents something like 3 per cent. of the total number of out-patients. In other hospitals a like stringent inquiry takes place, with equally commendable results."

I am, Sirs, yours faithfully,

April 12th, 1897. G. P.

THE NOTIFICATION OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In the account of my paper read before the Epidemiological Society on the Prevention of Tuberculosis given in your issue of April 3rd one or two misapprehensions have occurred.

I did not say that congenital tuberculosis rarely, if ever, occurred. The words "if ever" should be omitted. I did not admit that notification of phthisis had been tried in Manchester and had failed. Notification in any proper sense has not been tried in Manchester. Less than thirty cases were, I understand, submitted to the Health Office for purposes of disinfection, which was then taken to mean chiefly fumigation. This is not intended to minimise the excellent work of education done by Dr. Ransome, but to prevent an unjust aspersion being put on notification, its objects and its uses.

I am, Sirs, yours faithfully,

Manchester, April 9th, 1897. JAMES NIVEN.

DEBT-COLLECTING ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—Several complaints having reached my society concerning the methods adopted by certain so-called associations professing to have been formed for the purpose of collecting medical debts, my society will be glad to hear from any of your readers who have had dealings with any of such associations and who are dissatisfied with their procedure. An association of the kind referred to, which has especially been brought under the notice of my society, has changed its name and address so frequently that it is difficult to suppose that inconvenience has not been caused to members of the medical profession.

I am, Sirs, yours faithfully,

HUGH WOODS,
Hon. General Secretary.

The London and Counties Medical Protection Society, Limited,
12, New-court, Lincoln's-inn, April 12th, 1897.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE PREVALENCE OF VENEREAL DISEASE AMONGST THE BRITISH TROOPS IN INDIA.

To the Editors of THE LANCET.

SIRS,—I am directed to inform you that at their last meeting the President, Vice-president and Council of the Royal College of Surgeons in Ireland passed the following resolution: "We, the President and Council of the Royal College of Surgeons, being deeply impressed by recently ascertained facts concerning the development and alarmingly increased prevalence of venereal disease amongst British troops in India, and also the apparently exceptional virulence of the malady there, are strongly of opinion that the time has arrived when some active steps should be taken by the Government to check the disease, not alone in the interests of those primarily affected, but of their immediate descendants and of the community at large in India and the United Kingdom. The facts recently elicited by the Departmental Committee presided over by Lord Onslow the President and Council of this College consider as nothing short of appalling, and such as to imperatively require that an effort should be made at once to check and mitigate the evil, as otherwise the public health in these countries, not merely in the present, but in the future, will be seriously imperilled."

I am, Sirs, yours faithfully,

ROBT. H. WOODS, F.R.C.S. Irel.,
Secretary of Council.

Dublin, April 7th, 1897.

THE INTERNATIONAL CONGRESS OF MEDICINE, MOSCOW, 1897: A GOOD ARRANGEMENT.

To the Editors of THE LANCET.

SIRS,—It is probable that many London and provincial medical men will attend the Congress at Moscow, from Aug. 19th to 26th. There is always a certain amount of trouble and inconvenience in arranging isolated parties of twos and threes, and it occurred to me that it might be a pleasant arrangement if those of us who are going from this country were to form a party and go together. I have been in communication with Messrs. Thomas Cook and Son, who have been most obliging, and they have prepared a programme at an inclusive fare of 45 guineas each person, providing for first-class travel tickets from London, *viâ* Berlin and Warsaw, to Moscow, returning *viâ* St. Petersburg, Helsingfors, Stockholm, Copenhagen, and Hamburg, Flushing, London, with hotel accommodation consisting of breakfast, luncheon, dinner, and bedroom, lights and service, restaurant and sleeping-car accommodation, free conveyance of 56 lb. of luggage, fees to hotel and railway servants, *and the services of a competent conductor*, who will superintend the travelling arrangements throughout. Messrs. Cook and Son's terms are so reasonable that I hope many will be prepared to join the party. Messrs. Cook and Son will send a detailed programme to anyone applying, and will be pleased to answer all questions.

I am, Sirs, yours faithfully,

ARTHUR G. BLOMFIELD, M.D. Aberd.

Exeter, April 12th, 1897.

"THE ESSENTIALS OF CHEMICAL PHYSIOLOGY."

To the Editors of THE LANCET.

SIRS,—In the review of the above book, published in THE LANCET of April 10th, I notice that your reviewer blames me for introducing no mention of the application of Lovibond's tintometer to the estimation of the corpuscles and the colouring matter of blood. May I be allowed to point out that the book in question was published in the early part of last year, prior to the publication of Dr. George Oliver's work on this question? I was perfectly well acquainted with the principles of Dr. Oliver's new hæmoglobinometer at the time, but it was obviously impossible for me to publish prematurely what Dr. Oliver had been doing. Your reviewer is in error when he speaks of the applications of the tintometer to the enumeration of the corpuscles. Dr. Oliver's hæmocytometer is sold by the Tintometer Company, but it has no further relation to the tintometer of Lovibond.

I am, Sirs, yours faithfully,

April 10th, 1897. W. D. HALLIBURTON.

"TINNED SALMON."

To the Editors of THE LANCET.

SIRS,—Will you permit me to call your attention to the enclosed notices from the *Manchester Courier* and the *Manchester Guardian* of what took place in the police-court of that city on the 26th ult. The Charles Wood therein referred to is the person who wrote a letter to the *Globe*, from which you quoted and upon which you commented in your issue of the 20th ult., under the heading of "Tinned Salmon." Having regard to the motives which actuated the writer of the letter in question we feel that we are justified in asking you to explain to the readers of your much valued journal that the source from which the damaging reports emanated is, to say the least, an entirely unreliable one. We need hardly point out that a reproduction of a false report by a publication of the authority and influence of THE LANCET is in the highest degree damaging to the interests of those engaged in the trade.

The tinned fish trade has developed enormously, and it is computed that not less than 20,000 tons is annually consumed in this country. The packing of the canned salmon is carefully watched by the Canadian Government, and the out-turn on this side is very critically and thoroughly inspected in the ordinary course of trade by experts before a single tin is offered for sale. In fact, the trade have recognised that it must, in their own interest, be their first duty to protect the consumer, and it would under present conditions be quite impossible for such fish as described by the *Globe* correspondent to reach the public. We notice your article has been reproduced and quoted in other publications, which, although of comparatively little importance in themselves, yet when mentioned in connexion with the name of your paper cannot fail to be seriously regarded. We very sincerely hope that you will see your

Hosted by Google

way to inform your readers of the unreliable source from which the information in the first instance arose.

I am, Sirs, yours faithfully,
(For J. Travers and Son, Limited),
London, E.C., April 9th, 1897. H. STABLEFORTH.

*** We noticed Mr. Wood's letter, published in the *Globe* of March 10th, in our issue of March 20th because of the startling statements it contained, but we expressed a doubt as to the accuracy of the details, seeing that the statements had been categorically denied.—ED. L.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

VII.—COVENTRY.[1]

Predominance of the Working Class Subscribers.—The Visiting Staff and the Out-patients.

THE question of working-class control in the management of hospitals, which is causing so much discussion in Leeds, has also been ardently debated in Coventry. Nor is this a new difficulty. So far as Coventry is concerned, it dates back to the year 1889; and, of course, it is intimately associated with the problem of hospital abuse. At the annual meeting of subscribers to the Coventry and Warwickshire Hospital, held in 1883, four governors were elected from the Working Men's Hospital Saturday Committee. That was the best moment for protestations, for it was then that the principle of working-class representation was established. The number of working men representatives and the amount of their subscription were then so small that their admittance seemed to be merely a question of courtesy instead of an act likely to produce far-reaching practical consequences. It was not till the year 1889 that the possible effects began to be realised. In May of that year a proposal was brought before the general committee, which is the managing body of the hospital, demanding that for every £20 the workmen subscribed they should be empowered to elect one governor. The rule of the hospital is that "all persons being subscribers of one guinea or more annually shall be governors during payment." In 1888 the workmen had subscribed more than £900, and yet only appointed four governors. To elect a governor it had cost the workmen over £230, though the ordinary subscriber became a governor at the cost of only one guinea. As a compromise between these two extremes it was proposed to give the workmen a governorship for every £20 subscribed. This would have placed forty-five working men representatives on a body consisting of 450 governors. On the financial basis the workmen might have claimed a larger representation; but as far as could be ascertained they seemed well satisfied with this compromise. A general meeting of governors was convoked to discuss the matter, and readily adopted a resolution that the number of working men on the general committee should be increased from four to six. This was illogical, for if working men are to be excluded as governors why should they be admitted on the managing committee. The discussion displayed considerable class feeling. It was said that the middle classes subscribed to provide a hospital for the working class, and that as the middle classes did not derive any benefit from it they ought to control the institution. The answer made was that in that case obviously the working-class ought not to be asked to subscribe. Also it was pointed out that the middle and upper classes did derive benefits from the hospital, for they not infrequently went there themselves, and often sent their servants. The alarm was also raised that the hospital would become a provident dispensary. In looking back at the records of this dispute I find much that confirms what I have already stated with regard to a similar movement at Leeds. For instance, the following passage from the first leading article in the *Coventry Herald* of May 19th, 1889, is almost identical with the description I gave of the feeling at Leeds: "It need not be wondered at if the Saturday collection should to some extent have fostered the idea that those contributing to it thereby establish special rights. The hospital is very properly held up as a working man's interest, and when working men subscribe to it the further step to a sense of proprietorship is easy. A penny a week to the provident dispensary gives such and such privileges; why not the same at the hospital? They are both medical institutions, and both exist for the benefit of the working class. If this reasoning is fallacious we must admit that it is also natural, and therefore in a measure inevitable."

To the claims set up by the working men it was objected that the hospital buildings and plant had cost about £25,000 and the working men had not contributed anything to this capital outlay. On the other hand, the majority probably of the present guinea subscribers had also not contributed to this original capital outlay, and yet they were governors. Another argument was based on the belief that the honorary medical staff were opposed to the innovation, and the time, skill, and knowledge they devoted to the care of the patients were more valuable than the £900 contributed by the workmen. Nobody, however, denied this, and any claim the medical staff might have made to a voice in the management of the hospital would have been received with favour. At the meeting of the governors convened to discuss the whole question Dr. Milner Moore urged that for years people had been in the habit of receiving charity from the hospital and that of late only had they been stirred to such a sense of self-respect as led them to contribute to the hospital at first £200 in a year and now £900. But they had at the same time received the benefits of the institution. The medical staff received no return for the work they gave. In large centres like London or Birmingham there was an advantage in belonging to a hospital. A medical man might there become a professor and a consultant and derive advantage from his students, who in after life called him in. This was not the case in the smaller towns where there was no clinical school. The original subscribers to the Coventry Hospital, who had devoted hundreds of pounds to build it up, never intended that it should become a provident dispensary for persons able to pay, and he thought that by increasing the working-class representation they were drifting in that direction. Mr. Iliffe urged that this tendency would drive medical men in self protection to demand payment for the services they rendered at the hospital—a suggestion which was received with cheers. He thought workmen who earned £2 or £3 a week could afford to pay for medical attendance, and he objected to granting them a governor's rights for every £20 they subscribed "because under such a plan the time would come when those who freely gave their donations would be overwhelmed in the administration of the institution. Coventry was a growing city and sooner or later the adoption of this proposal would convert the hospital—erected as a refuge for the poor—into one gigantic provident institution." In spite of these two protests the resolution was only defeated by a majority of one—16 to 15. This was such a small vote and such a small majority that it was decided to submit the question to all the governors, a poll having been demanded.

Pending the day of the poll the controversy was resumed, notably by the local press, and some communications were also addressed to the medical journals on the topic. Protests were made that subscriptions, whether large or small, conferred no rights on the patients, that it was easy to understand the dissatisfaction of the medical men who gave their services gratuitously when they found the penny a week subscriptions flung, as it were, in their faces. The honour of the working men as a class was appealed to and they were urged to put an end to so unworthy a conception. If they wanted a return for their pennies, then the benefit societies or the provident dispensaries were open to them. It could not, however, be denied that the dispensary idea did prevail among many of the hospital patients. This found its origin not so much in the Saturday collection, but rather in the fact that for every guinea subscribed three letters of recommendation to the hospital were given. In 1888 the Working Men's Committee had received 2586 tickets, and thus the connexion between paying and receiving had been established. Then, again, it was pointed out that, whereas the middle-class governors of the hospital took but little interest in the

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; and (6 *concluded*) Feb. 13th, 1897, Leeds.

Hosted by Google

work, rarely attended meetings and rarely voted, the forty-five workmen, if they were appointed, would attend regularly and vote as one man. This, though undoubtedly true in fact, was a poor argument to adduce, as it is difficult to evoke sympathy for people who fail to attend to their own affairs.

The worst feature of the matter has still to be mentioned: the workmen's subscriptions, in the majority of cases, though theoretically voluntary, are in practice compulsory. Taking the evidence of workmen themselves this is how the matter is explained by a journeyman watchmaker whose letter the *Coventry Herald* published on May 31st, 1889: "They say that it is a rule made by the men—a rule of the shop—and can be altered if not liked. This rule was made three or four years ago, because workmen had been urged by certain gentlemen at hospital annuals. Say, then, a man this year makes application for employment, he gets put on; he is told of this rule, but is also told that he need not pay if he don't like—that it is voluntary. He is compelled to pay because others pay, and he would be marked among his mates and boycotted, so he keeps his mouth shut and pays, glad to get employment on such terms. Say, however, he is told it is voluntary; then the rule would be a lax one. Soon it would be whispered A, B, and C don't pay—then why should I pay?—and the whole concern would pretty well soon fall to the ground, for it would not hold together six months, much more three or four years; but, say all of them are loyal and keep loyal, then, sir, they deserve all they ask for, even if it is only a tribute to their self-denial."

This workman then goes on to complain that certain gentlemen for several years patted his class on the back and urged them to show their independence. When the workmen take this hint to the extent of subscribing £900 a year, then these same gentlemen turn round and, as the writer describes it, say: "Oh, come, we did not bargain for this; this is too much. You must keep as you were. You must let us patronise you. You haven't got the same intelligence as we have to manage a large institution like a city hospital. It was built expressly for you, not for us; then it is impudence of you to want to share in its management." Thus we have the dilemma: Either the workmen are independent donators—and in that case they claim to have the same share in the management of the hospital as is given to the middle-class donators—or else they are not independent; then they ask for a return for their money on the provident dispensary principle.

Such were some of the arguments with which the governors of the hospital had to deal. As if to confirm the argument that a small body of workmen would override a large body of middle-class men because of the lack of discipline and the negligence of the latter, barely more than 10 per cent. of the governors went to the poll. In this small poll the majority in favour of the working men's claim was in the proportion of two to one. At the last moment the opposition made by the honorary medical staff of the hospital completely broke down and the workmen and their friends swept the boards. From that day for every £20 collected among working men a working-man governor of the hospital has been appointed.

Since this eventful decision the population of Coventry has greatly increased. A large number of workmen have come to this town so as to profit by the "bicycle boom," and the workmen's subscriptions for the year 1896 amounted to £1300. Consequently there are sixty-four elected working-men governors and six *ex-officio* working-men governors. The subscribers of a guinea and upwards amount in all to 560 or thereabouts; but though these latter are also governors and still constitute a vast majority, it is, as foreseen, the working-class element that is the active element. Thus it may now be said that no medical man could be elected on the staff of the hospital if the working-classes were opposed to him. The recent election of a surgeon to the hospital staff was carried by the working class vote. To avoid this Dr. Moore, consulting surgeon at the hospital, had proposed that the medical officers of the hospital should be appointed by a special committee of selection to be nominated by the general committee which manages the hospital. But a working-class representative at once moved an amendment to the effect that such a course would reduce the privileges of the subscribers. Dr. Moore urged that it was an expensive matter for a candidate to canvass an electorate of some 600 persons; also such canvassing was a means by which medical men might unfairly advertise themselves. On the pretext of canvassing for his election a new comer or a comparatively unknown practitioner might call on all the donators to the hospital, and in soliciting their vote would have an excuse for expatiating on his own merits. Then he could also appeal to the public in the local papers, always in view of the election. Finally, as the new comer or unknown practitioner would have no serious chance of being elected he might magnanimously withdraw at the last moment. In the meanwhile a good advertisement would have been secured. Then, again, it was urged that the better class of subscribers did not like the annoyance of being canvassed. These arguments were met by the working men representatives. The latter declared that if appointments were entrusted to a small and special committee such a body would be sure to incur the suspicion of jobbery. If the high-class subscribers objected to be canvassed the working people who were also subscribers had no such objection; then as the workmen constitute the majority of the patients it was very natural that they should wish to have a voice in the appointment of the medical men. These arguments prevailed, and Dr. Moore's proposal was rejected. Thus once again the workman element was master of the situation.

While the working classes are increasing their hold on the hospital the usual subscribers and donators are showing some lukewarmness. Thus for the year 1896 the income of the hospital from all sources amounted to £3374 8*s.* 4*d.*, or £57 16*s.* 6*d.* less than the previous year. But while the general sources of income fell off the workmen's subscriptions, which amounted to £1000 in 1895, rose to £1300 the year following. But for the extra £300 given by the workmen the condition of the accounts would have been little short of calamitous. The workmen have contributed more than a third of the total receipts of the year; their subscriptions are ever increasing, while the donations from the other classes were last year £123 less than the former year, the collections in country parishes £10 18*s.* less, and the legacies £70 less. There can be no doubt that the voluntary subscriptions given by the middle and upper classes are declining in the face of the working-class subscriptions. A local practitioner with whom I discussed this matter said that there did not seem energy enough remaining even to organise a bazaar for the hospital. On the other hand, he maintained that the workmen resented the pressure put upon them by their employers or foremen, by which they were obliged to subscribe their penny a week. These enforced subscriptions engendered the conviction that the subscriber had a right to go to the hospital, and they are indignant when the hospital they pay for is described as a charity. What is compulsory cannot be a charity. The workman who has been forced to subscribe asks whether the gas which burns in the street and for which he is forced to pay rates is also a charity. The impression is gaining ground that the imposition of what is nominally a subscription, but in reality a tax, must tend towards the municipalisation of hospitals, for the voluntary element is dying out. This impression is based on the fact that the workmen's subscription has increased from £132 in 1874, when it was started, to £540 in 1884, to £1000 in 1894, and to £1300 in 1896, that the other subscriptions are declining and now represent less than two-thirds of the total income. The workmen who find themselves compelled to pay will naturally feel resentful against those who do not pay. If the tax were compulsory everywhere, a penny a week on all adult males would bring in about enough to support the hospital without any voluntary subscription whatsoever. So long as a hospital was supported by the subscriptions of a few rich persons it could be justly considered as a gift—a charity; but if a hospital is to be supported, paid for, and maintained by everybody, and if everybody is to have a voice in its management, it is not surprising if some persons think the day is not so far off when such a hospital will be looked upon, not as a private charity, but as public property. There will not then be far to go before reaching the municipalisation of hospitals. Such in any case is the forecast which the present situation at Coventry suggests, and naturally, as the charitable element disappears, the necessity of paying the whole medical staff becomes more and more obvious.

With such large subscriptions coming in from workmen who in many instances believed that by subscribing they acquired a right to go to the hospital, it was to be anticipated that there would be a great deal of hospital abuse. The staff, however, took a wise measure to check such abuse. They decided that the out-patients should be seen only by the

Hosted by Google

house surgeon and the assistant house surgeon. The out-patients come in the morning. When there is a very serious or complicated case, and a second opinion is thought necessary, the patient has to return in the afternoon and is then seen, in consultation with the house surgeon, by one of the honorary visiting staff. In other towns people throng to the hospitals so as to obtain what they conceive to be superior advice, even though they are often suffering only from some ordinary or trivial complaint. A person who can pay a 2*s.* 6*d.* or 3*s.* 6*d.* fee goes to the hospital so as to obtain advice from a consultant to whom he would have to pay a guinea if he applied to him privately. This cannot be done at Coventry, as advice from the visiting staff is, as already stated, only obtained in exceptional cases. According to another rule, no member of a club or medical aid society can obtain advice at the hospital unless he brings a letter from his club medical officer. In practice this means that a club patient can only come to the hospital for a second opinion. Then even the visiting staff do not enjoy a much higher reputation than the other practitioners of the town, so there is not the rush for superior advice which in larger centres causes much hospital abuse. On the other hand, there is no method of inspection to prevent abuse. The house surgeon is supposed to ask questions, and the former house surgeon did ask a good many questions, with the natural result that he became proportionally unpopular. It is impossible to expect that a young house surgeon, especially if he hopes ultimately to set up in practice, should ask many questions. Thus it amounts to this, that few questions are asked unless a case threatens to become very troublesome, then it is worth while to see whether the patient is justified in coming. Many Coventry patients, however, go to the Birmingham hospitals, though they could well afford to pay the fees of the Coventry practitioners. The tendency of the patients is to go to a large centre. In the smaller provincial towns, where every medical man is a general practitioner, the highest standard of work cannot be so easily attained, and this tends to render hospital abuse less frequent. Perhaps it is more prevalent among the in-patients of the Coventry hospital. To prevent this no one is admitted as an in-patient unless he has six recommendations, whereas one suffices for the out-patients. Even the patients who come with a letter from a medical man are asked to get recommendation tickets as well, and are only admitted without them when the case is very urgent. As, however, three recommendations are given for every guinea subscribed, they are not difficult to obtain, and at the end of the year many subscribers still have unused tickets remaining. The medical staff is opposed to the ticket system, but the workmen want a *quid pro quo* for their subscriptions. The public has been so thoroughly educated to the ticket system that it is thought the subscriptions would be very greatly reduced if the system were abolished. A very few paying patients are admitted, the charge is generally a guinea per week, but I have not heard that this has given rise to any particular complaint. Though I have listened to the bitterest denunciations of the abuse prevailing at the Coventry Provident Dispensary, there is comparatively little said about abuse at the hospital so far as the patients are concerned. The great question at Coventry is the advent of the working men as the preponderating influence in the future of the hospital.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Royal Institution for Deaf and Dumb Children.

THE Royal Institution for Deaf and Dumb Children held its annual meeting on April 9th. The Lord Mayor (Mr. James Smith) presided. The report stated that important extensive alterations had been made during the past year at a cost of £4000. The institution now provided accommodation for 102 boys and 82 girls, the number on the register being 147, which has since increased to nearly the full complement. The balance-sheet showed the total receipts to have been £4483 odd, and this amount had been exceeded in the expenditure by £30 odd. Two-thirds of the amount received from scholars come from the School Board, the Government insisting upon the recognition by the school boards of the deaf and dumb children of the country. Lord Calthorpe was elected president and the usual votes of thanks were passed. The system of education and management of this institution has always received commendation, the school being considered to be one of the best of its kind in the kingdom.

Country Holidays for Town Children.

Sir Willoughby Wade presided at the fourth annual meeting of this useful society on the 11th inst. He pointed out that, with the exception of an infinitesimal expenditure on incidental expenses, all the money contributed was applied directly to the objects for which it was collected. Out of £616 raised last year, the outgoings for incidental expenses only amounted to £34. They could not but recognise what an advantage it was to the health of the children for them to have a free run in the country, and though their visit only extended to a fortnight the effect was not temporary, but lasting. The civilising influence of the holidays was also an important feature. An additional advantage which accrued from the holidays was educational, as the novel surroundings of the children elicited thought and imparted new ideas. A fortnightly holiday was provided at a cost of 11*s.*, including railway fare, but a large amount of labour was given by the ladies who interested themselves in the movement. The Bishop of Coventry was elected president for the ensuing year. It was mentioned that last year the children themselves contributed £208 towards the expenses.

Queen's Hospital.

Dr. Suckling has resigned his position as physician to the hospital after fifteen years' service. It is hoped that he will be elected on the consulting staff, as a recognition of the important and valuable services which he has rendered.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Sewage Problem.

THE difficulties with which Manchester has to contend in the disposal of its sewage were fully set forth at a meeting of the Manchester Statistical Society held on March 31st, when a paper making definite practical suggestions was read by Mr. Nathaniel Bradley, J.P., F.C.S., a member of the city council. At present 26,000,000 gallons of sewage have to be dealt with every day, the effluent from which, after treatment at Davyhulme with chemicals and precipitation, is discharged into a nearly stagnant portion of the Ship Canal. In passing under review the various methods of sewage disposal Mr. Bradley commenced with filtration through land, but dismissed it with the remark that it was out of the question in the case of Manchester, because the necessary quantity of land was not available, and even if it could be obtained it would be of a kind that would be unworkable and probably a source of infection to the whole neighbourhood. The two remaining plans were disposal either by the Ship Canal or by an underground culvert leading to the Mersey where it became tidal. At Davyhulme precipitation was at present effected by the addition of milk of lime, and subsequently by the addition of copperas (protosulphate of iron), about seven grains of each being added to every gallon of sewage. On the present system of sludge pressing and working (without artificial filters) the cost of this treatment averaged £2 2*s.* per million gallons; in London the cost was £2 9*s.* 6*d.* per million gallons. In a report published in 1893 Mr. J. Carter Bell, F.I.C., analyst for the county borough of Salford, gave a description of twenty various sewage processes which were tried at the Salford sewage works, but after four years of experiments not one of them was adopted by the Salford Committee, either because the effluent soon set up secondary putrefaction or because the cost was prohibitive. Notwithstanding reiterated assertions to the contrary, the precipitate from sewage has no commercial value as manure. The Local Government Board in August, 1894, issued a return called for by the House of Commons, containing information on the subject from about 220 districts in England and Wales in which systems of treating sewage by precipitation were in use; 160 of them had no sale whatever for their precipitated sludge; sixty places had a slight sale at prices from 6*d.* to 2*s.* 6*d.* per ton; in two or three places the price was 3*s.* per ton. The filtration of sewage through three feet deep of cinders or finely broken clinkers, weighted

Hosted by Google

down with a six-inch top layer of gravel, obtained from the State of Massachusetts the name of "bacteriological method," and there was an artificial filter called the septic tank, which was said to purify sewage by means of bacteria and practically to form no sludge. The London County Council constructed such a filter an acre in extent, and their chemist, Mr. Dibdin, made experiments on these bacteriological lines at the northern outfall works at Barking. The Manchester Rivers Committee were also attracted to this bacteriological process and erected two small filters for experiments at Davyhulme. The Corporation of Glasgow had previously sent representatives to various places in England to obtain information, and had had under consideration all the known systems of sewage purification that were of importance. In the light of this knowledge sewage works were opened at Dalmarnock, the eastern district of Glasgow, in May, 1894, capable of dealing with 10,000,000 gallons per day. The buildings, railway sidings, tanks, and filtering beds covered an area of nineteen acres; the land cost £38,000, and the buildings, tanks, and machinery an additional £67,000, or £105,000 in all. This was substantially the so-called bacteriological treatment on an extensive scale, inasmuch as the sewage after precipitation was filtered through cinders and sand. After three years' experience, however, the Glasgow Corporation decided that this filtration was inapplicable in the case of a large community, and they have recently obtained Parliamentary authority for discharging their effluent into the tidal waters of the river Clyde. London also has discontinued the bacteriological filter, and conveys the effluent to the tidal waters of the Thames. Mr. Bradley therefore concludes that Manchester will be under the necessity of constructing a culvert leading to the tidal waters of the Mersey.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Bristol.

AT the meeting of the Bedminster (Bristol) board of guardians held on March 23rd it was decided, by 21 votes to 8, that the board should adopt the recommendation of the Royal Commission on Vaccination and allow persons having conscientious objections to vaccination to make a statutory declaration before a magistrate of such objection, and that such a declaration duly made would bar proceedings. One guardian, in opposing the resolution, very wisely remarked that they as a board had no power to adopt such a resolution, as they were there to administer the law as it stood. Unfortunately, however, his advice was not taken.—The new infectious diseases hospital at Ham Green, under the control of the sanitary authority of Bristol, is rapidly approaching completion. It will have four wards and an isolation ward in separate buildings 40 ft. apart. Each of the four wards will contain seventeen beds. The isolation ward is divided into four apartments, with two beds in each. The total cost is about £27,000. The establishment will be lighted by electricity.

The late Dr. Brabazon.

A handsome painted glass window has been recently placed in the Church of St. Mary, Bathwick, as a memorial to the late Dr. Anthony Beaufort Brabazon of Bath, who died in March, 1896. The window is executed in the manner of the fifteenth century, and contains large figures of St. Luke the Evangelist and of SS. Cosmas and Damian, also patron saints of medical men.

Small-pox on Board Ship.

At Cardiff Police-court on March 26th the master of the Norwegian steamship *Parisien* was fined 20*s.* and costs for failing to send notice to the medical officer of health of the Cardiff port sanitary authority that he had on board a person suffering from small-pox.

Death of Mr. J. C. Christison Beddoe.

The particulars of the death of Mr. J. C. C. Beddoe, the only son of Dr. Beddoe, F.R.S., of Bradford-on-Avon, have now reached this country. Mr. Beddoe had an accidental fall amid the Quaebac Hills on Jan. 12th, and died before assistance reached him. He held a responsible position in Major Lugard's African exploring expedition to Lake Ngami. The greatest sympathy is felt for the bereaved parents.

University College of South Wales and Monmouthshire.

A special meeting of the Council of this College was held at Cardiff on March 24th, under the presidency of Dr. Sheen, for the purpose of appointing a professor of anatomy. The three selected candidates appeared before the Council, and eventually Mr. A. Francis Dixon, B.A. Dub., M.B., B.Ch., B.A.O. Trin. Coll., Dub., was appointed to the vacant chair. Professor Dixon has for the past four years held the post of chief demonstrator of anatomy in the University of Dublin; previously he had worked for three years in the zoological laboratories of Trinity College, Dublin, and of the Royal College of Science, Dublin, and obtained the gold medal and senior moderatorship at the examination for B.A. in 1889 at the University of Dublin.

Proposed Cottage Hospital for Chippenham.

It is proposed to commemorate the Queen's Diamond Jubilee at Chippenham by the erection of a cottage hospital. The scheme originated with Sir J. Dickson Poynder, who has subscribed £500 for the purpose. The Mayor will shortly make an appeal for funds, which will doubtless receive a generous response.

Proposed New Hospital for Barry.

The Barry urban district council, at the meeting on April 2nd, decided to recommend to a town's meeting that by way of commemorating the Queen's Jubilee a general hospital should be provided for the town out of the rates, but in the first instance that an accident hospital be erected and also a permanent home for the Barry Nursing Association.

New Convalescent Home at Llanfairfechan.

The Heath Memorial Convalescent Home at Llanfairfechan, North Wales, was opened recently. It has been erected at a cost of about £20,000 by Messrs. Robert James and Arthur Heath, as a memorial to their father, Mr. Robert Heath, the well-known ironmaster.

April 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Graduation Ceremonial.

THE spring graduation ceremonial of the University of Edinburgh took place on the 13th inst. The following well-known gentlemen received the honorary degree of LL.D.: Professor James Dewar, F.R.S., of the Royal Institution, London; Emeritus Professor Sir Douglas Maclagan, F.R.S. Edin.; Mr. John Rae, M.A., of London; the Right Hon. Lord Russell of Killowen, Lord Chief Justice of England; and Mr. John Wyllie, M.D., F.R.C.P. Edin. In presenting Dr. Wyllie the Dean of the Faculty of Law said that he (Dr. Wyllie) had acted for fifteen years as physician to the Royal Infirmary, but Dr. Wyllie's title to the honour which was to be conferred upon him rested mainly upon the remarkable scientific work which he had achieved.

Glasgow Medico-Chirurgical Society.

The April meeting of the society was held on the 2nd inst., the chair being taken by Mr. H. E. Clark. Dr. George H. Edington showed a boy on whom he had performed Excision of the Ankle three years ago for tuberculous disease after several partial operations had failed. The excision was done through a transverse incision extending across the dorsum of the foot from the external to the internal malleolus. The astragalus was removed entirely, the cancellous tissue of the os calcis was scooped out, and a slice taken from the lower end of the tibia and fibula. On two or three subsequent occasions a small sinus in the cicatrix needed attention, but otherwise the result was satisfactory. The boy retains a useful foot, and in walking with his boots on it is impossible to distinguish the affected limb. There is no ankylosis. Dr. Edington also showed a boy whose tarsus had been entirely removed with the exception of a limited portion of the os calcis. The operation was performed eleven months ago, and the boy can now walk with a barely perceptible limp. The foot is much shortened, but there is considerable freedom of movement both between the os calcis and the metatarsus and between the leg bones and the os calcis. In the discussion on these cases there was a general consensus of opinion in favour of partial operation rather than

Hosted by Google

amputation for tuberculous disease affecting the feet in children, though amputation as securing prompt and certain removal of the entire disease and more rapid healing of the wound was not without its advocates. Dr. Crawford Renton and Dr. Snodgrass submitted notes of a case in which abdominal section was performed for rupture of a gastric ulcer. There were unusual difficulties attending the diagnosis and the operation could not be completed, the explanation, as found on post-mortem examination, being that adhesions between the stomach and the diaphragm rendered access to the ulcer impossible. Dr. Renton also showed a patient on whom he had successfully operated for gastric ulcer. The clinical notes of the case were submitted by Dr. Adamson, who drew attention to the following points: (*a*) the slight degree of shock which was manifested and the rapidity with which evidences of this disappeared, so that it was difficult to convince the patient that an operation was necessary; (*b*) the board-like rigidity of the abdominal wall; (*c*) the diminution of the hepatic dulness without evidence of tympanitic distension of the abdomen; (*d*) the presence of a tinkling sound over the upper abdomen; and (*e*) the complaining of pain—doubtless a referred pain—above the clavicles. Dr. J. H. Nicoll showed the following:—(*a*) two specimens of Paget's Disease of the Nipple; (*b*) the Parts removed from a case of Strangulated Interstitial Inguinal Hernia; (*c*) Vermiform Appendix Removed with an Abscess Cavity containing it; and (*d*) an Encysted Vesical Calculus.

Medical Appointments.

Henry A. Watson, M.A., M.B. Glasg., who has just completed a period of service as house physician in Professor Gairdner's wards in the Watson Infirmary, has been appointed house surgeon to the Royal Hospital for Sick Children, Glasgow.—Geo. A. Turner, M.D. Glasg., has resigned his appointment as physician for Diseases of Women in the Central Dispensary, Glasgow. Dr. Turner was recently elected to the corresponding position in the dispensary of the Watson Infirmary.—Geo. Balfour Marshall, M.B. Edin., has been appointed Government Visitor at the examinations of the Pharmaceutical Society held in Edinburgh, in succession to Sir Douglas Maclagan, M.D., resigned.

April 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE Council of the College has nominated Mr. William Thomson (president), Mr. Swan (vice-president), Sir Charles Cameron (secretary), and Sir William Stokes to represent the College at the Moscow International Congress.

The Apothecaries' Hall in Ireland.

The Apothecaries' Hall has recently received from the Privy Council of England notification of the result of its appeal against the decision of the General Medical Council, which body refused to appoint examiners in surgery for the qualification of the Hall. The Privy Council has allowed the appeal and directed the General Medical Council to appoint such examiners.

The Adelaide Hospital, Dublin.

Dr. W. J. Smyly, who has recently finished his term of office as master of the Rotunda Lying-in Hospital, has been elected obstetric surgeon to the Adelaide Hospital, in succession to Dr. Purefoy, the present master of the Rotunda.

Belfast Board of Guardians.

The results of the recent elections just declared show that a lady has been returned at the head of the poll for one of the principal wards of the city.

Londonderry Asylum Board.

The secretary of the board of control in Dublin has intimated to the governors of the Londonderry Asylum that the Treasury have sanctioned a loan of £110,000 for the erection of a new asylum at Gransha for the Londonderry district, the periods of repayment and rate of interest to be as follows: £102,000 in fifteen years, at 3½ per cent. per annum; £7700 in twenty years, at 3½ per cent. per annum.

Death of Professor Townsend of Cork.

The death on the 11th inst. of Dr. Edward Townsend has been the cause of general regret in Cork medical circles. Though suffering from heart disease and aneurysm, he had been actively engaged in his profession within the past fortnight. Educated at Trinity College, Dublin, he graduated in the year 1857, and succeeded his father in a large practice in Cork. He was senior physician to Cork South Infirmary and County Hospital, physician to the Cork Lying-in Hospital, and consulting physician to the Hospital for Protestant Incurables, and in all these institutions his work gained esteem for him. In 1888 he was appointed Professor of Medicine at the Cork Queen's College, and his lectures were much appreciated by the students for their lucidity, erudition, and happy selection of illustrative cases.

April 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Academy of Medicine.

THE discussion upon appendicitis was continued last week at the Academy of Medicine, but much of its interest was lost, as nearly all that could be said had been said. M. Potain supported M. Dieulafoy in saying that he, unlike M. Lucas Championnière, M. Reclus, and surgeons in general, had never seen appendicitis as a consequence of entero-colitis. On this question the different surgeons and physicians joined issue, and apparently each intends to retain his personal view. At the same meeting M. Brouardel gave an account of the part that he played at the recent International Sanitary Conference at Venice, and discussed the conclusions that the delegates had arrived at.

The Service Médical de Nuit.

Another, the fifth, Commission of the Municipal Council of Paris has been instituted, on the proposition of M. Fourest, to arrange for the organisation of a gratuitous medical service between the hours of 5 P.M. and 10 P.M. It is well known, on the one hand, that the medical officers of the charity organisations are not obliged to visit the sick after 5 P.M., and, on the other hand, that the *Service Médical de Nuit* only comes into action after 10 P.M. Recent events have called attention to the inconvenience of this interregnum. The same Commission of the Municipal Council has been approached by M. Breuille, who desires a modification of the rules of the service, so that if one district should be overcrowded it should have the right to apply for medical assistance to a less crowded district of the same arrondissement. At the sitting of the municipal council on Monday last M. Edmond Gibert read a report on the petition of a Doctor Da Costa Leite who protested against the situation in which some medical men were placed who had undertaken the duties of the *Service Médical de Nuit.* Dr. Da Costa Leite stated that he had made nineteen night visits during January and up to Feb. 15th inclusive, during which time the new night service had been definitely at work. The new organisation would credit him with 75 fr., which amounted to 3 fr. 95 c. per visit. Dr. Da Costa Leite thought that having accepted the proposals of the Préfecture of the Police that he should guarantee his services during the night in the district where he resided he ought not to be victimised to this extent. It will be remembered that originally the officers of the service received 10 fr. for each visit.

Death of Dr. Maisonneuve.

One of the most illustrious surgeons of the century, Maisonneuve, whom a large number of people thought to be dead, on account of the silence which has shrouded his name for many years past, has just departed this life, aged eighty-seven, at his chateau of Missillac, Loire Inferieure, where he had lived in retirement for the last eight years. Born at Nantes in 1810, Jacques Gilles Maisonneuve became resident medical officer at the Paris hospitals, and afterwards prosector at Clamart. In 1840, after a brilliant *concours*, Maisonneuve was nominated surgeon to the Cochin Hospital. Thence he transferred his services to the Pitié, and finally to the Hôtel Dieu. He soon became noted as the most skilful surgeon of his time, being particularly well known for the number of surgical instruments which he invented, and some of which—for instance, the urethrotome—are still in use under his name. Maisonneuve was the first surgeon to perform the operation of resection of the hip-joint, while his

Hosted by Google

conservative surgery was as sensational as his operative. In 1862 he showed before the Academy of Medicine the case of a young engineer whose leg he had preserved by the practical application of the physiological theories of Flourens as to the reproduction of bone by the periosteum. In this case he removed the fractured tibia, retaining the periosteum, out of which a new tibia was formed. Since 1875 he had retired from the practice of his profession so entirely that, as I have already said, many even in his own country thought him to be dead.

April 13th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Inter-Academic Courtesies.

TO-DAY will set out from Milan *en route* for Berlin a company of 350 students and graduates representing every seat of learning in Italy. They are drawn from every faculty, law and medicine preponderating, and are under the guidance of several well-known occupants of university chairs. The medical group, for example, is conducted by Professor Porrando of Genoa and Professor Panzeri and Professor Sormani of Pavia. The trip is organised by the University Association of Pavia, and its object is to afford the renascent schools of Italy an opportunity of witnessing the *modus operandi* pursued at one of the most splendidly equipped and efficiently organised centres of culture, whether theoretical or practical, in Europe. Nothing but good can come of the object lesson thus presented; indeed, its underlying conception and its realisation are among the most hopeful symptoms observable in the evolution of Young Italy. From having been the mother and mistress of modern learning she has lapsed into being the daughter and pupil; but as a first step to regain the ground she has lost she sends a chosen band of her best *alumni* to visit the advanced posts of inductive research and professional qualification, so that on their return these youths may report to their respective schools the impressions they have received and the suggestions they have gathered, with a view to making profitable innovations on their backward traditions. While Berlin is the final goal of the trip, a good many other seats of learning will be visited going or coming—for instance, Zürich, Heidelberg, Cologne, Leipzig, and Munich. In future years these academic excursions will venture further afield, and the universities or provincial schools of the British Isles and the United States are already set down for eventual visits. London has on more than one memorable occasion extended her scientific or professional hospitality to foreign guests, her International Congresses of Hygiene and Demography and of Medicine and Surgery being still quoted as models of what such gatherings should be. These, it is true, she organised for the proficients, or the "past-masters," in science and in its practical application; but when the time comes for the young graduates and advanced students to pay her their contemplated visit she will prove equal, I do not doubt, to her best traditions, and add another to the many pleasant experiences which her Italian guests particularly delight to recall.

"Enlighten the Mothers."

This is the watchword of an organised attempt to realise in Italy the ideal so well formulated by the late eminent Commissioner in Lunacy, Sir James Coxe: "Let every child be taught to become the intelligent custodian of its own health." The Palazzo Gaetani has for some time been the centre of attraction for all interested in the organised attempt aforesaid, Dr. Minossi addressing there considerable audiences, mainly female, on Pronto Soccorso (First Aid), which he handles in a popular yet essentially scientific and practical style. On the medical side of the subject he dealt yesterday with microbic infection, and startled his hearers with the announcement, drawn from official returns, that in Italy 200,000 persons die every year from infective—that is, from preventable—maladies, and that of those victims the majority are young, "the hope of families, the resource of the coming generation." If mothers of households were properly alive to the danger and to the preventability of these maladies, a first step would be taken towards minimising this annual death tribute, and by way of showing what means they may command for such an end Dr. Minossi gave clear and impressive descriptions of the genesis, course, and culmination of the more familiar infective maladies, assisted by preparations which made his meaning unmistakeable. He was effectively supported by representatives of the various cliniques, by numerous consultants, general practitioners and advanced students, and also by well-known leaders of society, all of them in hearty sympathy with the undertaking, of which he is one among its numerous medical promoters.

The Return of Winter in Italy.

The last four months have been peculiarly trying on the Riviera Ponente and even the Riviera Levante, what with rain, occasional snow, and the intermittent sting of the east wind. And now, just as spring was attempting a "transformation scene," winter has again put in an appearance, greatly to the disappointment of visitors to the attractive towns of the Alta Italia and the Italian lakes. On the 9th inst. at Savona a violent storm, accompanied with dense hail showers, burst over the neighbourhood, the hail in some spots lying half a foot deep and doing immense damage to fruit trees in blossom. At Brescia the cold is Siberian, again caused by the heavy hail all over the province; and at Pallanza—"the Nice of the Lago Maggiore," as it is happily called—a correspondent tells me, the climate is once more "that of January," so torrential has been the rainfall, so frequent the snow-storms on the heights, and so piercingly cold the winds. Matters are still worse on the Swiss side of the Alps, where the frost has injured irreparably the fruit trees and vineyards. The travelling Briton should therefore think twice before exchanging the comforts of home for the imprisonment of a sub-Alpine or north Italian hotel.

April 10th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The X Rays and Anatomical Preparations.

PROFESSOR DIAKONOF[1] discusses the use of the Roentgen rays in preparing photographs, or radiographs, of anatomical preparations. Structures like arteries, veins, bronchi, and broncheoles may be injected with various materials more or less opaque to the x rays, and the resulting radiograph shows with perfect accuracy their relative distribution. The best material for injecting is mercury, on account of the ease with which it can be manipulated and the fact that the same injecting fluid can be used over and over again. When it is wished to inject two sets of vessels in the same organ and to show their distribution in the radiograph mercury may be injected into one set and a still more opaque material into the other. The following mixture is suggested: of gypsum, cinnabar, and red lead, twenty parts each; of flour, ten parts; add enough water to make the mixture sufficiently fluid to flow into the smallest vessels. This mixture is too opaque, and the resulting shadows in the skiagraph too black, to be recommended as a substitute for mercury, but it is useful in combination with it as a contrast.

A Balneological Congress.

It is proposed to hold during the year 1898 a Russian conference upon balneology and climatology. It will be one hundred years next year since the mineral springs of the Caucasus, still the best known and most frequented of Russian spas, were discovered, or, to speak more accurately, since they came to be used therapeutically. The proposal to mark the centenary by holding such a conference originated with the Russian National Health Society, and a committee has been elected to make the necessary arrangements. Foreigners who attend the International Congress in Moscow this summer will have an opportunity, if they can spare the time, of seeing the group of watering-places in the Caucasus just alluded to. A fortnight's tour through the Caucasus, details of which have already appeared in THE LANCET,[2] has been arranged for members of the Congress, and as the itinerary of the tour allows for a stay of two days at Kislovodsk this will permit those who wish to visit Essentuki, Piatigorsk, and Jeleznovodsk, which with Kislovodsk are the most important centres of this great group of springs.

[1] Chirurgia, February, 1897.

St. Petersburg and the International Medical Congress.

The town council of St. Petersburg has voted a sum of 5000 roubles (over £500) for expenses in entertaining the members of the International Medical Congress. Part of this sum will probably be spent in the publication of two guides to the city—one general and one medical.

Fatal Fire at an Asylum.

A fire broke out on the evening of March 16th (28th) in a lunatic asylum in the town of Yaroslavl. A ward containing forty female patients was completely destroyed, and three of the patients lost their lives in the flames. The remainder succeeded in escaping.

A Conference on Water supplies.

St. Petersburg might well be termed a city of conferences. A useful one was held here last week to discuss the question of water-supplies to communities. The members were chiefly hygienists, engineers, and municipal representatives, who discussed the different aspects of the main question at a series of meetings prolonged over six days. A new project for the water-supply of St. Petersburg, which is at present admittedly unsatisfactory, was the subject of prolonged debate.

The Cost of Providing for Lunatics.

The municipality of St. Petersburg has voted the sum of 1,000,000 roubles (over £100,000) to the building and maintenance of new lunatic asylums in the capital.

April 12th.

Obituary.

MARK ANTHONY FENTON, M.D. T.C.D., L.R.C.S. IREL., &c.

DR. M. A. FENTON, medical officer of health of Coventry, died at his residence at Coventry on April 6 h. He had been in indifferent health for some time past and was compelled to relinquish his work upon March 27 h. Eventually pneumonia developed, from which, although nursed and tended with every care, he was unable to rally. He was educated in Dublin, and his first appointment was that of resident medical officer to the Worcester Dispensary. After this he was appointed house surgeon to the Coventry and Warwickshire Hospital, a post he held for two years, and upon relinquishing it was elected one of the medical officers to the Coventry Dispensary, a position he continued to hold until the day of his death. The chief work of his life, however, and that for which he will ever be gratefully remembered by the citizens of Coventry, was sanitary. Appointed medical officer of health in 1874, at a time when the death-rate was 27 per 1000, Dr. Fenton never rested or spared himself in his efforts to improve the sanitary conditions of the city. How well he succeeded may be judged from the fact that at the time of his decease the death-rate had been reduced to 16 per 1000. A health committee was appointed at his request, isolation of infectious cases when they did occur was thoroughly carried out, and the building of the City Hospital was entirely due to his exertions. In all sanitary matters he was looked to as a leader in the district, and he held the post of President of the Birmingham and Midland Association of Medical Officers of Health; he was also a Fellow of the Society of Medical Officers of Health and medical officer to the City Hospital for Infectious Diseases. He contributed a paper to the *Sanitary Record* for 1880 upon Infantile Mortality, and another to *Public Health* in 1888 upon the Elementary Education Act as a Factor of Infectious Disease. Dr Fenton married in 1874, and leaves a widow and several children.

PTOLEMY SAMUEL HENRY COLMER, M.D. DURH., L.R.C.P. EDIN., L.F.P.S. GLASG., L.S.A.

DR. P. S. H. COLMER of Yeovil died suddenly on April 8th. He had been subject to epileptic attacks for the past year, although with the aid of his son, Mr. P. A. Colmer, he still continued his professional duties. The deceased received his medical education at Anderson's College, Glasgow, and took the qualifications of L.R.C.P. Edin. and L.F.P.S Glasg. in 1862. In 1882 he graduated M.D. of Durham University. Dr. Colmer had an extensive practice, and was highly respected by the inhabitants of Yeovil. He took the greatest interest in all public affairs connected with the town, having been a member of the corporation for over twenty years, and at the time of his death held the position of alderman He had been mayor of Yeovil on four occasions. He was a borough magistrate, a member of the school board, the board of guardians, and the Somerset County Council. He was an honorary medical officer of the Yeovil District Hospital and surgeon to the majority of the friendly societies in the town. The deceased, who was fifty-six years of age, leaves a widow and several children, for whom much sympathy is felt.

THOMAS CARLYLE BEATTY, M.R.C.S. ENG., L.S.A. LOND.

SEAHAM HARBOUR has sustained a severe loss by the death, at the age of eighty-three years, of Mr. Thomas Carlyle Beatty, who had been for upwards of half a century a much-respected and hard-working practitioner in that town. The deceased was the son of the late Dr. William Snow Beatty of Hull, and was educated at Glasgow University, where he was, like his immediate predecessor and life-long friend Benjamin Ward Richardson, a prizeman in every class. He began practice at Easington, in the county of Durham, but early in 1850 removed to Seaham Harbour, where he obtained the appointment of surgeon to the Marquis of Londonderry's collieries of Seaham and Seaton. He filled all the public appointments and was Admiralty surgeon to the Seaham district for more than forty years. He was a surgeon to the Seaham Harbour Infirmary and Surgeon-Lieutenant-Colonel in the 2nd Durham Artillery Volunteers, having held a commission in this celebrated regiment from the beginning of the Volunteer movement, and he was one of the first Volunteer officers to receive the decoration. At the special request and by the influence of Colonel the Marquis of Londonderry he was enabled to retain his commission long after the usual time for retirement, but a few years ago he felt obliged, owing to failing health, to send in his resignation much to the regret of all the officers of the brigade. Mr. Beatty became deaf early in his career, which probably prevented his attaining that higher eminence in his profession which his distinguished University career and his great ability might have brought within his reach. He, however, had considerable reputation as an able general practitioner. He was a generous friend to the poor, and a great part of the work of his practice was done gratuitously.

Mr. Beatty had been a widower for some years before his death. He leaves two sons, both in practice as medical men, and four daughters, three of whom are married. The funeral took place on April 6th at Seaham Cemetery, and was attended by a large number of relatives and friends.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination in April the following candidates passed in the subjects indicated:—

PART I.

Biology.—C. F. Bluett, St. Bartholomew's Hospital; S. F. Hickman and C. Hind, Royal Free Hospital; F. H. Maberly, Birmingham; M. Malcolm, Royal Free Hospital; E. Osborne, Birmingham; H. Richardson, Leeds; and C. M. Scott and M. E. Unwin, Royal Free Hospital.

Materia Medica and Pharmacy.—R. R. P. S. Bowker, Middlesex Hospital; M. E. Fendick, Royal Free Hospital; W. H. Gale and A. H. Gibbon, St. Thomas's Hospital; B. Hogan, London; G. R. Lucas, Edinburgh and St. Bartholomew's Hospital; C. C. Morgan, St. Bartholomew's Hospital; H. Munro, Guy's Hospital; F. Robinson, Royal Free Hospital; J. Welsh, Dublin; H. F. Willington, Manchester; and L. Wright, St. Thomas's Hospital.

PART II.

Anatomy.—H. J. Aldous, King's College Hospital; T. P. Allen, St. Bartholomew's Hospital; W. Asten, Birmingham; E. O. Balleine and A. St. J. Bateman, King's College Hospital; A. F. Carlyon, Middlesex Hospital; E. L. D. Dewdney, King's College Hospital; M. E. Fendick, Royal Free Hospital; C. Fisher, St. Bartholomew's Hospital; J. S. Goodall, Middlesex Hospital; J. E. Griffith, St. Bartholomew's Hospital; H. M. Hardy, Guy's Hospital; R. J. Harris, St. Thomas's Hospital; W. G. Hopkins, St. Mary's Hospital; F. A. Hort, Cambridge; D. Jeaffreson, St Bartholomew's Hospital; H. Jessop, Birmingham; J. McOlinock, King's College Hospital; C. J. Marsh, University College; E. R. Millar, University College

Hospital; H. E. Morris, Guy's Hospital; F. Robinson, Royal Free Hospital; H. Smith, Birmingham; A. C. S. Waters, Cambridge; J. Welsh, Dublin; B. B. Westlake, Guy's Hospital; H. E. Weston, St. George's Hospital; A. H. Wilson, Birmingham; J. P. Woodhouse, Liverpool and Durham; and T. Young, St. Bartholomew's Hospital.

Physiology.—M. A. Alabone, Guy's Hospital; H. J. Aldous, King's College Hospital; T. P. Allen, St. Bartholomew's Hospital; A. St. J. Bateman, King's College Hospital; S. F. Cheesman and C. E. C. Child, Charing-cross Hospital; H. H. Cotman, Aberdeen; M. B. Dawson, Middlesex Hospital; M. E. Fendick, Royal Free Hospital; C. Fisher, St. Bartholomew's Hospital; J. S. Goodall, Middlesex Hospital; W. H. Goodchild and J. E. Griffith, St. Bartholomew's Hospital; H. M. Hardy, Guy's Hospital; R. J. Harris, St. Thomas's Hospital; W. G. Hopkins, St. Mary's Hospital; D. Jeaffreson, St. Bartholomew's Hospital; H. Jessop, Birmingham; J. McClintock, King's College Hospital; E. R. Millar, University College Hospital; H. E. Morris, Guy's Hospital; R. C. Morris, Birmingham; D. V. Muller, Charing-cross Hospital; W. A. Pitt, Edinburgh; C. V. Smith, University College Hospital; H. Smith, Birmingham; A. C. S. Waters, Cambridge; J. Welsh, Dublin; B. B. Westlake, Guy's Hospital; H. E. Weston, St. George's Hospital; A. H. Wilson, Birmingham; W. R. Wilson, Dublin and Belfast; and T. Young, St. Bartholomew's Hospital.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the First Examination for the degree of Bachelor in Medicine at the College of Medicine, Newcastle-upon-Tyne, in April, the following candidates satisfied the examiners in the subjects indicated:—

OLD REGULATIONS.

Chemistry with Chemical Physics.—Robert Tilbury Brown, M.R.C.S., L.R.C.P., and Gerald Burton Brown, L.S.A., Guy's Hospital; Gilbert Smith, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; John Henry Tripe, London Hospital; Thomas John Augustus Tulk-Hart, M.R.C.S., L.R.C.P., Guy's Hospital; and Percy Edward Turner, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.

NEW REGULATIONS.

Elementary Anatomy and Biology, Chemistry, and Physics.—Second-class Honours: James Willie Heslop, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Robert Story Brown and George Burrows Brown, College of Medicine, Newcastle-upon-Tyne; Howard Payne Fox, Cooke's School of Anatomy; and Charles William Turner and Frederick Percy Wigfield, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—Annie Tombleson Brunyate, London School of Medicine for Women; Bernard Edward Granville Bailey, St. Bartholomew's Hospital; Frederick Clarkson and Samuel Thomas Cochrane, College of Medicine, Newcastle-upon-Tyne; William Claughton Douglass, St. Bartholomew's Hospital; Albert Ernest Hodge, College of Medicine, Newcastle-upon-Tyne; Evan Llewellyn Jenkins, Cooke's School of Anatomy; William Pattullo, Edinburgh School of Medicine; Stanley Raw, College of Medicine, Newcastle-upon-Tyne; Leonard Satchwell Smith, Mason College, Birmingham; and William Waters Stainthorpe, Ralph Thomas Vaux, and Frederick George Wilson, College of Medicine, Newcastle-upon-Tyne.

Anatomy and Biology.—Alice Maud Dodd, London School of Medicine for Women; James Farrage, College of Medicine, Newcastle-upon-Tyne; Ida Emilee Fox and Cbella Mary Hankin, London School of Medicine for Women; Frederick Percy Joscelyne, Yorkshire College, Leeds; Guy Hannah Kirby, Mason College, Birmingham; Florence Dyer Durell Ledgard, London School of Medicine for Women: Michael Joseph Quirke, Mason College, Birmingham; and Hugh Widdas, College of Medicine, Newcastle upon-Tyne.

Elementary Anatomy, Chemistry, and Physics.—Mary Jane D'Vaz, London School of Medicine for Women, and David Henry Jeavons Kirton, Mason College, Birmingham.

Elementary Anatomy.—Otto Charles Henry Leopold Moll, Guy's Hospital, and Theophilus William Morcom, London Hospital.

PROPOSED KURSAAL FOR CHELTENHAM.—At a meeting of the Cheltenham Town Council held on April 5th, Mr. Ward-Humphreys, M.R.C.S. Eng., L.R.C.P. Lond., introduced a scheme for the demolition, or at least the removal, of the glass and brick structure of the present Winter Garden, and the erection of a kursaal and municipal buildings on the site at a cost of £48,000. After a lengthy discussion the plans were passed.

LITERARY INTELLIGENCE.—Messrs. Rivington, Percival, and Co. announce for early publication a small volume entitled "Some Aspects of Infantile Syphilis," being the Hunterian lectures delivered at the Royal College of Surgeons of England in 1896, by J. A. Coutts, M.B. Cantab., M.R.C.P. Lond., physician to the East London Hospital for Children.—The first number of a new Portuguese medical journal, entitled *Archivos de Medicina*, has reached us. It is edited by Dr. Camera Pestana, of Lisbon, and is to appear on the 25th of every month. The issue before us contains original articles on the Diagnosis of Diphtheria and on Malarial Psychoses, and some reviews; also a table of the results of anti-diphtheritic serum treatment during January from the Lisbon Bacteriological Institute, there being only two deaths in nineteen cases.—Mr. Grant Richards announces the publication of a series of portraits by Mr. Will Rothenstein of literary and artistic persons.

MERTHYR TYDVIL GENERAL HOSPITAL.—Lord Wimborne has promised a donation of £1000 towards the Diamond Jubilee Ward of this hospital.

MR. ODED LOWSLEY, public vaccinator of the Reading district, has just received from the Local Government Board the sum of £101 2*s.*, as an award for efficient vaccination.

TAUNTON NURSING ASSOCIATION.—At the annual meeting of the Taunton Nursing Association which was recently held it was stated that 941 cases had been treated during 1896, necessitating nearly 16,000 visits. The maternity branch had dealt with 258 cases.

ST. JOHN AMBULANCE SOCIETY.—Mr. Hermann Rogers-Tillstone, M.D., C.M. Aberd., of Clevedon, Somerset, has been elected a life member of the St. John Ambulance Society in recognition of his services in delivering gratuitous courses of lectures on "First Aid" and "Nursing."

CHARING-CROSS HOSPITAL.—A meeting of the Special Appeal Committee of Charing-cross Hospital was held in the board-room on April 11th. Donations amounting to £23,450 were announced, including £1000 to endow a bed from a patient of Dr. Travers, of 2, Phillimore-gardens, Kensington.

BRISTOL MEDICAL MISSIONARY SOCIETY.—The annual meeting of this society was held on March 23rd. The report showed that 7252 patients had been treated at the mission, the attendances numbering 22,793, and that 1506 patients were visited at their homes. The honorary secretary stated that additional funds were needed, for the ordinary contributions were from £130 to £150 below the ordinary expenditure.

HOSPITAL SATURDAY AT BRISTOL.—At a meeting of the Bristol Joint Hospitals Committee it was decided that in anticipation of the numerous demands to be made upon the purses of the public during the year of Her Majesty's Diamond Jubilee, the committee will suspend the street collections for the current year, but they hope to receive contributions from organisations and individuals who may be disposed to assist the funds of the local medical charities. The ladies and other helpers of last year will be requested to continue their good offices on future occasions.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—The committee of the Hospital for Consumption and Diseases of the Chest, Brompton, have issued an appeal for a sum of £20,000 to be employed in providing a country branch in connexion with the hospital. It is hoped that a suitable site may be given free of cost by some benevolent person, and the committee's proposal is to erect separate cottage buildings, each of which will accommodate ten or twelve patients, with probably a separate bedroom for each, and also with apartments for the attendants. An endeavour will be made to obtain Her Majesty's permission to call the new branch "The Victoria (Country) Branch of the Brompton Hospital for Consumption." Contributions may be sent either to the treasurer, Mr. W. S. Deacon, 20, Birchin-lane, or to the secretary, Mr. W. H. Theobald, at the Hospital, Fulham-road, S.W.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the winter session 1896-97:—Descriptive Anatomy—Junior: J. F. Peart, first; W. R. Meredith, second. Senior (two prizes): J. S. P. Stewart and Miss F. A. Dreaper, first; J. S. P. Stewart and Miss F. A. Dreaper, second. Practical Anatomy—First year: A. S. Ellenbogen, first; J. F. Peart, second. Second year: J. S. P. Stewart, first; Miss F. A. Dreaper, second. Third year: G. W. Little, first; J. M. M. Crawford, second. Practice of Medicine: D. A. Fitzgerald, first; S. R. Godkin, second. Theoretical Surgery: A. S. Green, first; F. J. Palmer, second. Midwifery: F. J. Palmer, first; D. Hadden, second. Physiology: J. S. P. Stewart, first; Mrs. H. L. Hennessy, second. Theoretical Chemistry: J. P. Byrne, first; J. P. O'Donnell, second. Pathology: W. H. May, first; P. H. Falkner, second. Physics: E. Glenny, first; S. Gordon, second. The summer session commenced on Thursday, April 1st, for the three months' course of operative surgery, practical chemistry, histology, pharmacy, public health and forensic medicine, materia medica, biology, and uncertified dissections.

FOOTBALL CASUALTY.—On Saturday last, in a match between Batley and Widnes, one of the visiting team of players had his right leg "fractured, or dislocated near the ankle," and was carried off the field.

PRESENTATIONS TO MEDICAL MEN.—The following gentlemen have been the recipients of presents for honorary instruction given to their respective ambulance classes, namely: Mr. Francis Ward, M.B., C.M. Edin., senior house surgeon at the Ipswich and East Suffolk Hospital, from the Orwell Works ambulance class, a handsome silver "Tantalus," bearing a suitable inscription; Mr. James Adamson, M.D. Glasg., of Hetton-le-Hole, Durham, from the ambulance classes at Hetton-le-Hole, an electro-plated tureen and vegetable dish; and Mr. John J. Adams, M.D. R.U.I., of Ashville, Antrim, from the St. John Ambulance Class, Antrim, a silver cigar-case, cigarette-case, and a match-box.—Mr. C. St. John Wright, M.B., C.M. Aberd., M.R.C.S. Eng., on his resignation of the office of medical superintendent of the infirmary and medical officer of the workhouse of St. Mary's, Islington, after fifteen years' service, received on March 25th in the board-room an illuminated testimonial on vellum, framed, from the guardians, justices of the peace, and in-door and out-door officers, as a mark of the respect in which he was held by all with whom he was officially associated. The address states that a silver candelabrum was at the same time presented to Dr. Wright. This is a magnificent piece of plate of solid silver with four branches, and bears an inscription round the base stating the facts and dates of Dr. Wright's long connexion with the infirmary and the workhouse.—Mr. John Sutherland, M.B., C.M. Edin., of Netherfield, Nottingham, has received the gift of a travelling bag from the members of the Colwick Branch of the St. John Ambulance Association as a token of appreciation of his First Aid instructions.—In the course of a musical entertainment at the Recreation Hall of the Melton Asylum, Suffolk, on the 27th ult., which was well attended by the patients, staff, and several visitors, Mr. W. Eager, L.R.C.P. Lond., M.R.C.S. Eng., the resident physician and superintendent of the asylum, who is leaving after many years' service, was presented with a solid silver salver and a silver tea-service. The salver was the gift of the present staff, and the tea-service of the past officers, of the asylum.—Mr. George Black, M.B., B.S. Lond. of Hurstpierpoint, Hassocks, Sussex, has received the present of a handsome walking stick as an acknowledgment of his gratuitous lectures to the Hurst Ambulance Classes.—At the recent grand *finale* in connexion with the Fraserburgh Mutual Improvement Association, held in Dalrymple, Mr. Archibald Dingwall, M.B., C.M. Aberd., past president of the association, was presented with an illuminated address on the occasion of his leaving Fraserburgh. An honorary life-membership of the society was at the same time conferred upon him.—Mr. T. Carson Fisher, M.D. Dub., and Mr. William G. Armstrong, M.B. Syd., D.P.H. Camb., medical officers of the Berrima District Hospital, New South Wales, have each been presented with an honorarium of 25 guineas.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Midwives Registration Bill.

AN attempt was made after midnight on Thursday, April 8th, to obtain a second reading for the Midwives Registration Bill, but it failed, and the order was put down again for Monday, May 3rd.

Irish Poor Relief Bill.

The Bill to amend the law in Ireland with regard to the relief of the destitute poor was formally introduced on Thursday, April 8th, by Mr. Gerald Balfour, Chief Secretary to the Lord-Lieutenant.

Removal of Bodies.

In view of the Committee stage of the Public Health (Scotland) Bill an amendment has been drawn up by Mr. Caldwell, proposing that it shall not be lawful to transport the body of any person who has died from an infectious disease by railway or other public conveyance, not being a conveyance reserved for such purpose, unless and until the medical officer has certified that every precaution necessary for the public safety has been adopted to his satisfaction.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 7TH.

Marking of Foreign Meat.

This sitting of the House was occupied with a second reading debate upon a measure for the marking of foreign meat and cheese, and for the registration of persons who deal in these commodities. The Bill differs from the measure of last session in several respects, but notably in this, that it does not propose that small sections of meat and cheese should be marked, but only carcasses, or sides, or hams, or the rinds of cheese. In the course of the debate an hon. Member put forward the idea that frozen meat was a cause of cancer, but Dr. Farquharson assured him and the House that any such apprehension was entirely out of the question. The Bill was read a second time and referred to a Select Committee.

THURSDAY, APRIL 8TH.

The Army Medical Service.

Captain Norton asked the Under Secretary of State for War whether the Army Medical Service was at the present time sufficient, not only for mobilisation, but for medical military needs at home and abroad, and, if not, whether any steps were being taken to increase the staff.—Mr. Brodrick replied that the establishment of officers of the medical staff was about forty under strength. Measures to make good this deficiency were now under consideration.

Mr. Bartley asked whether it was not the case that the officers on the retired list were as numerous as those on the active list, and whether steps would be taken to remedy this state of things.—Mr. Brodrick said that the officers on the retired list were employed on the home service, and there were complaints in consequence that the officers on the active list were debarred from employment on the home stations.

The Troops in India.

Captain Pirie asked the Secretary of State for India what steps, if any, had been taken to carry out the urgent recommendation of the Sanitary Commissioner with the Government in India, in his report for 1894, which was also quoted with approval in the Report on Sanitary Measures in India in 1894-5, that much might be done to diminish the extent and severity of contagious diseases among the British troops in India by providing increased facilities for bathing with comfort and convenience in private and public baths, and by inculcating habits of personal cleanliness among the troops.—Lord George Hamilton replied that he had received no special report as to the action taken on representations made by the Sanitary Commission in 1894, but he understood that in the opinion of the military authorities ample provision was made for supplying British soldiers in India with the means of personal cleanliness. The importance of the matter was so well understood in India that it would hardly be necessary to call for any special report.

Oysters in Relation to Disease.

Sir William Priestley asked the President of the Local Government Board whether, in view of the report published last year concerning oyster culture in relation to disease and the diminished consumption of oysters which had resulted therefrom, he proposed to have oyster beds regularly inspected, or to adopt such other measures as would give the public a reasonable assurance that oysters in the market were derived from healthy sources and not likely to be the cause of disease.—Mr. Chaplin replied that the subject of this question was one of great importance. It presented, however, many difficulties. The inspection of the oyster beds in this country would not in itself secure the result suggested, and the question had to be considered in connexion with oysters imported from abroad as well as those obtained from English beds. Any scheme to be effective would require legislation, but the subject was receiving his careful consideration.—Sir William Priestley asked whether in localities where oyster beds and pits had been certified to be contaminated by sewage any steps would be taken to improve their condition.—Mr. Chaplin replied that without notice of the question he could not say what steps were or were not to be taken by local authorities.

Verminous Persons Bill.

At this sitting the Bill conferring powers as to the cleansing of verminous persons was read a second time.

MONDAY, APRIL 12TH.

Relief for Army Medical Officers.

Dr. Farquharson asked the Under Secretary of State for War whether, seeing how short-handed the Army Medical Department was at home, and the difficulty of getting leave, he would arrange some system of relief, so as to enable medical officers to obtain relief according to regulations.—Mr. Powell Williams, who replied for the Under Secretary, said he was happy to be able to inform the hon. Member that arrangements were in progress which it was hoped would afford greater facilities to military medical officers for obtaining leave.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ABBOTT, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Tooting Workhouse of the Wandsworth and Clapham Union.

ANDREW, J. GRANT, M.B., C.M. Glasg., has been appointed Assistant Surgeon to the Victoria Infirmary, Glasgow.

BEHRENDT, M. R. J., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Brumby and Frodingham Urban District Council.

BOX, CHARLES RICHARD, B.Sc., M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Resident Assistant Physician at St. Thomas's Hospital, vice Seymour G. Toller.

BRISCOE, W. T., M.D. Dub., M.Ch., has been re-appointed Medical Officer of Health by the Chippenham Town Council.

BUCH, JOSEPH, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Hunslet Rural District Council.

BURGESS, E. A., M.R.C.S., has been appointed Medical Officer for the Thorncombe Sanitary District of the Beaminster Union.

CRADDOCK, S., M.R.C.S., has been appointed Medical Officer to the Cottage Home Schools of the Bath Union.

DIXON, A. FRANCIS, M.B., B.Ch., B.A.O. Dub., has been appointed Professor of Anatomy at the University College of South Wales and Monmouthshire.

FOSTER, H. G., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Swaffham Rural District Council.

FRANCIS, G. P., L.R.C.S. Edin., L.A.H. Dubl., has been re-appointed Medical Officer by the Brecon Rural District Council.

HAMERTON, G. A., F.R.C.S. Eng., has been appointed Medical Officer to the Inland Revenue Department, Somerset House, London.

HARVEY, GEO., L.R.C.P. Edin., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Matlock Bath Urban District Council.

HOME, GEORGE, M.D., has been appointed a Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

JENKINS, T. W., M.D., C.M. Glasg., has been appointed Assistant Surgeon to the Victoria Infirmary, Glasgow.

JONES, M. R., M.D. Glasg., has been re-appointed Medical Officer for the Devynnock Sanitary District of the Brecon Union.

JONES, RICHARD, M.D. Edin., D.P.H. Camb., has been re-appointed Consulting Medical Officer of Health by the Merioneth County Council, and Medical Officer of Health by the Ffestiniog Urban District Council.

KEIR, W. J., F.R.C.S., L.R.C.P. Edin., has been re-appointed Medical Officer by the District Council of Melksham.

KINGDON, J. R., B.A. Camb., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Weston-super-Mare Hospital and Dispensary, vice Gurney, resigned.

LOCKWOOD, JOSEPH, M.R.C.S., has been appointed Medical Officer of Health by the Whitley Upper Urban District Council.

LOW, CHARLES W., M.B., D.P.H., F.C.S., has been appointed Medical Officer of Health by the Stowmarket Urban District Council.

MACLEOD MUNRO, D. G., M.B., C.M. Edin., has been appointed Resident Physician to the Victoria Hospital for Consumption and Diseases of the Chest, Craigleith, Edinburgh.

MORCOM, A., L.R.C.S., L.M. Edin., has been re-appointed Medical Officer of Health by the Dunstable Town Council.

MORGAN, OWEN, L.R.C.P., L.R.C.S. Edin., L.F.P.S., L.M. Glasg., has been appointed Medical Officer for the Central District of the Newport Union, vice T. Limbery, deceased.

MURPHY, WM., M.B., C.M. Edin., has been re-appointed Medical Officer of Health by the Holbeach Urban District Council.

NETTLE, WILLIAM, M.R.C.S., has been re-appointed Medical Officer of Health by the Liskeard Town Council.

NEWMAN, GEORGE, M.D. Edin., C.M., D.P.H. Camb., has been appointed Medical Officer of Health for the Parishes of Charterhouse, Furnival's Inn, and Staple Inn, London.

PHILLIPS, S. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the North Peckham Sanitary District of the Camberwell Parish.

PINEO, E. G. D., M.R.C.S., L.R.C.P., has been appointed Provident Medical Officer to the Weston-super-Mare Hospital and Dispensary, vice A. L. Webb, resigned.

REES, D. V., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Brecon Urban District Council.

SMITH, W. T., M.R.C.S., has been re-appointed Medical Officer of Health by the Lepton Urban District Council.

SOUTHEY, A. J., M.R.C.S., has been re-appointed Medical Officer of Health by the Eton Urban District Council.

STEPHENS, JAS W., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Cardigan Town Council.

SYMES, W. S., L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Newbold Urban District Council.

TAYLOR, C. H., M.B. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Derbyshire Royal Infirmary, vice J. A. Sharp, resigned.

VERNON, WILLIAM, M.R.C.S., L.R.C.P. Edin., has been appointed Medical Officer for the Bitton District of the Warmley Union.

WADE, REGINALD, M.R.C.S., has been appointed Medical Officer of Health by the Highbridge Urban District Council.

WATERS, A. J. G., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the March Urban District Council.

WATTS, JAS. A. W., M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer to the Post Office at Hyde, vice G. W. Sidebotham, resigned.

WIGGINS, CHARLES, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Bexhill District Council.

Hosted by Google

WILLS, C., M.R.C.S., has been re-appointed Medical Officer of Health for the Borough of Newark.

WRANGHAM, WILLIAM, M.B. Lond., M.R.C.S., L.R.C.P., has been appointed an Assistant House Surgeon to the Leicester Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN.—House Surgeon, unmarried. Salary £80 per annum, with furnished apartments, board, gas, coals, and attendance.

BRIGHTON, HOVE, AND PRESTON DISPENSARY, Queen's-road, Brighton.—House Surgeon for the Northern Branch, unmarried. Salary £140 per annum, with furnished apartments, coals, gas, and attendance.

BURY DISPENSARY HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, residence, and attendance.

CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY, 41, Sloane-street, S.W.—Surgeon.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Resident House Surgeon for two years. Salary £100 per year, with board, apartments, and laundress.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY, Wakefield.—House Surgeon, unmarried. Salary £90 per annum, with board, lodging, and washing.

COMBINED DISTRICT OF BATTLE, CUCKFIELD, EASTBOURNE, &c.—Medical Officer of Health, for three years. Salary £600 per annum, to include all travelling and other expenses. Applications to the Secretary, Haywards Heath.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six months. Board, lodging, and washing provided in the hospital.

HANTS COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance. Applications to the Committee of Visitors, Knowle, Fareham.

HOSPITAL FOR SICK CHILDREN, Great Ormond street, Bloomsbury, London.—Assistant Surgeon. Also House Physician for six months. Salary £20, with board and residence in the hospital. Also House Surgeon for six months. Salary £20, with board and residence in the hospital.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £40 per annum, with board, lodging, and washing.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and Assistant Resident Medical Officer, for six months. A salary at the rate of £50 per annum for the senior post.

PARISH OF ROUSAY AND EGILSHAY, Orkney.—Resident Medical Officer. Salary £51 sterling per annum. Applications to the Clerk of the Parish Council, Rousay, Orkney.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board and lodging. Stimulants and washing not provided.

SEAMEN'S HOSPITAL SOCIETY (Dreadnought), Greenwich, S.E.—House Physician. Salary £75 per annum, with board and residence.

STOCKTON AND THORNABY HOSPITAL, Stockton-on-Tees.—House Surgeon, non-resident. Salary £200 per annum.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon for six months. Board, washing, and lodging in the institution provided.

WINDSOR ROYAL INFIRMARY.—House Surgeon, unmarried. Salary to commence at £100 per annum, with residence, board, and attendance.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon, for six months. Salary at the rate of £70 per annum, with rooms, board, and washing.

WONFORD HOUSE HOSPITAL FOR THE INSANE, near Exeter.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, and washing.

Births, Marriages, and Deaths.

BIRTHS.

DEVEREUX.—On April 11th, at North House, Tewkesbury, the wife of William C. Devereux, M.A., M.B., of a son.

GARDENER.—On April 10th, at Darley House, Sydenham, the wife of William F. Gardener, M.R.C.S., of a son.

MARRIAGE.

HOME—RICHARDSON.—On April 8th, at Holy Trinity, Upper Chelsea, by the Rev. A. L. Lilley, William Edward Home, Surgeon Royal Navy, to Ida Mary Geraldine, second daughter of the late J. Smith Richardson, Buncrana, co. Donegal, and of Mrs. Richardson, 41, Holbein House, Chelsea.

DEATHS.

WOODCOCK.—On April 9th, at Old Trafford, Jessie, eldest beloved daughter of Sam. Woodcock, M.D., aged 24 years.

IN MEMORIAM.

TOWNSEND.—On Sunday morning, April 19th, 1896, at 68, Queen's-gate, London, Mary Alice, only daughter of the late Thomas Ainsworth, of The Flosh, Cumberland, and for nineteen years the beloved wife of Thomas Sutton Townsend, of Clifton Manor, Warwickshire.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (24th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (21st).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. F. Enoch: Exhibition of Microscopical Entomological Specimens.

THURSDAY (22nd).—NEUROLOGICAL SOCIETY OF LONDON (Medical Society's Rooms, 11, Chandos-street, W.).—8.30 P.M. Clinical Meeting. Dr. Ferrier: A Remarkable Form of Nervous Disease occurring in Several Members of one Family.—Dr. Donkin: (1) A Man with Paralysis and Atrophy of one Leg; (2) A Boy with Paresis and Wasting of some Muscles of the Lower Extremities; (3) A Girl with Paresis and Paroxysmal Rigidity of the Lower Extremities.—Dr. Gossage: Progressive Muscular Atrophy commencing at the age of ten and a half years.—Dr. Lunn, Dr. Beevor, and Mr. Ballance: Cerebellar Tumour successfully Removed.—Dr. J. Taylor: Syringomyelia with Bulbar Symptoms.—Dr. Harris: Syringomyelia with probable Hæmorrhage into the Cavity.

FRIDAY (23rd).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The following cases will be shown:—Mr. C. J. Symonds: (1) A Case of Relapsing Myositis and Osteitis; (2) Subclavian Bruit in a Man aged twenty-five years; (3) A Boy from whose Jaw a Myeloid Sarcoma was Removed fifteen months ago without sacrifice of Bone.—Mr. F. Eve: (1) Congenital Dislocation of the Shoulder; (2) Arrest of Growth in Humeri.—Mr. H. Marsh: A Case of Hydronephrosis with Unusual Characters.—Dr. H. R. Smith: A Case of Amyotrophy of the Peroneal Type illustrating family predisposition to the affection.—Dr. J. K. Fowler: A Case of Myositis. Patients in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THURSDAY (22nd).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. W. C. Tyndale: House Drainage.

SATURDAY (24th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—Mr. T. Walker (conducted by): Inspection and Demonstration at Beddington Sewage Farm, Croydon.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

VERSION IN PREMATURE DELIVERY.

To the Editors of THE LANCET.

SIRS,—Will you kindly enlighten me as to when the above-named operation is deemed absolutely necessary, if it will not occupy too much of your time or space to do so, as the statements contained in text-books on the subject seem confusing? For instance, the operation of version (bipolar or internal) is described as if only applicable at or near term, while malpositions of the fœtus and accidental or unavoidable hæmorrhage are admittedly of frequent occurrence before term. One writer dismisses the subject of abortion during the fifth or sixth month with a few lines; another in a chapter on "Turning" says, "Of course, it is not necessary to turn a six months child"; while in a chapter on accidental hæmorrhage and when writing of its occurrence before term he says, "The child will be small and *unless lying transversely* its head or breach will come down into the cervix and dilate it," &c.; and further on, when speaking of the administration of ergot, "Ascertain first the position of the child, and *if transverse* correct it by abdominal palpation." In one sentence it is stated that "the uterus should not reach higher than half way between the ensiform cartilage and the umbilicus *after* the waters have escaped, and the head or breech presenting" (otherwise the position of the child is to be corrected); in another, "In short, in accidental hæmorrhage occurring before the uterus reaches higher than half way between the ensiform cartilage and the umbilicus, see that the canal is not contracted and that the child's long axis corresponds to that of the uterus. These conditions being present, *rupture* the membranes, put on a firm binder, and give ergot." I have emphasised the points which appear most confusing to myself.

I am, Sirs, yours truly,
April 5th, 1897. PERPLEXED.

*** Our correspondent's difficulty appears to us to arise from his endeavouring to establish any hard-and-fast rule as to when version should be performed. Each case must be considered on its own merits. Thus in placenta prævia the mother's safety is the chief consideration, and very possibly version may be the best means of dealing with a particular case. But it is not always necessary even in placenta prævia. The same applies to accidental hæmorrhage. Again, when premature labour is induced on account of contracted pelvis version is to be avoided if there is any reasonable chance of the child being delivered either spontaneously or with the forceps. But it may have to be resorted to. In cases of miscarriage at the fifth or sixth month in a normal pelvis the fœtus will probably be delivered whatever its position if there are good pains without any assistance; but if there is delay and the os is sufficiently dilated there can be no objection to seizing a foot and bringing it down. We believe if "Perplexed" will consider the circumstances of each case, instead of trying to have a stereotyped rule, he will have little difficulty in deciding as to when to perform version.—ED. L.

SMALL-POX AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—With regard to the history of vaccination I have never seen any allusion to the remarkable story told by Captain W. Butler (now General Sir W. Butler, K.C.B., F.R.G.S.), in the fourth edition of his book, "The Great Lone Land," 1873 (Sampson Low, Marston, and Co.). I will take the liberty of making extracts from General Sir William Butler's book, not only to further glorify Jenner for his discovery, but also with the hope that anti-vaccinationists, by the force of sane reasoning, some day may be driven to see the effect of small-pox on a nation unprotected by vaccination and the value of this great man's work.

"Small-pox, in its most aggravated type, had passed from tribe to tribe"—speaking of the British American (Canadian) Indians of Saskatchewan on pages 20-2-3—"leaving in its track depopulated wigwams and vacant council lodges; thousands (and there are not many thousands all told) had perished on the great sandy plains that lie between the Saskatchewan and the Missouri. ..... They knew nothing of this terrible disease; it had come from the white man and the trader. ..... For eighty years these vast regions had known at intervals the deadly presence of this disease, and through that lapse of time its history had been ever the same. ..... The camp moved away, but the dread disease clung to it—dogged it with a perseverance more deadly than hostile tribe or prowling war party; and far over the plains the track was marked with the unburied bodies and bleaching bones of the wild warriors of the West. The summer which has just passed had witnessed one of the deadliest attacks of this disease."

"Fort Pitt"—(pages 250-1) one of the Hudson Bay Company forts, about 1000 miles from Lake Superior towards the Rocky Mountains—"was free from small-pox, but it had gone through a fearful ordeal; more than 100 Crees had perished close around its stockades. ..... From a spot many marches to the south the Indians had come to the fort in midsummer, leaving behind them a long track of dead and dying men over the waste of distance. 'Give us help,' they cried, 'give us help, our medicine-men can do nothing against this plague; from the white man we got it, and it is only the white man who can take it away from us.' But there was no help to be given, and day by day the wretched band grew less. Then came another idea into the red man's brain: 'If we can only give this disease to the white man and the trader in the fort,' thought they, 'we will cease to suffer from it ourselves.' So they came into the houses dying and disfigured as they were, horrible beyond description to look at, and eat down in the entrances of the wooden houses, and stretched themselves on the floors, and spat upon the door-handles. It was no use, the fell disease held them in a grasp from which there was no escape, and just six weeks before my arrival the living remnant fled away in despair."

"I now enter upon that portion of your Excellency's"—the Hon. A. G. Archibald, Lieutenant-Governor of Manitoba (pages 366 and 368)—"instructions which has reference to the epidemic of small-pox in the Saskatchewan. ..... In the immediate neighbourhood of Fort Pitt two camps of Crees established themselves, at first in the hope of obtaining medical assistance, and failing in that—for the officer in charge soon exhausted his slender store—they appear to have endeavoured to convey the infection into the fort." This circumstance has been already alluded to. " ..... It is singular that only three persons within the fort should have been infected with the disease, and I can only attribute this to the fact that Mr. John Sinclair had taken the precaution early in the summer (1870) to vaccinate all the persons residing there, having obtained the vaccine matter from a Salteaux Indian who had been vaccinated at the mission of Prince Albert, presided over by the Rev. Mr. Nesbit, some time during the spring."

I am, Sirs, yours faithfully,
Canterbury, April 4th, 1897. PUGIN THORNTON.

Distress.—We sympathise with our correspondent, but we cannot answer questions which should obviously be addressed to her medical man. The condition is an obstinate one, from which immediate relief must not be expected.

O. C.—We never prescribe or recommend individual practitioners. Our correspondent must consult his own medical man.

Recovery is entitled under the circumstances to make his usual charges.

A MONSTER.

FROM Leghorn comes the announcement on the 8th inst. of the birth of a monster, the mother being a poor water-carrier of the city, and her offspring resembling from the head to the umbilicus a hare, and from the umbilicus to the lower extremities a normally developed infant. Dr. Botlari, who assisted at the birth, reports that the monster is alive; in place of eyes it has two cavities, its mouth and nose are similar to those of a hare, and it rejects by the one what is sent into the other and *vice versâ*. The mother volunteered the statement that during pregnancy in a house where she was carrying water she saw a hare cut up in quarters on the kitchen table, and was strongly impressed by the sight. Her health is good; while as to her offspring, in the more than probable event of its dying, it will be added to the local museum in illustration of the *lusus naturæ* which figure in Saint Hilaire's "Teratologie," as due to the impressionability of the pregnant.

A PLEA FOR THE CLIMATE OF THE CAPE PENINSULA IN CASES OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—So much has recently been written on the subject of South Africa as a health resort that some apology is almost needed for again bringing it before the profession. My excuse must be that in my daily practice I am constantly being made aware that a considerable amount of misconception still exists among English physicians on the subject. It is a most usual thing for patients consulting me on arrival in Cape Town, no matter at what time of the year it be, to say, "Where shall I go 'up country'? My doctor in England said, 'You must on no account remain in or about Cape Town.'" Now, I am very decidedly of opinion that phthisical patients arriving from England during the months October to March, as a rule, will do very much better by remaining in the Cape peninsula than by hurrying off to the excessive and trying heat of the higher altitudes of South Africa. This opinion, formed from my own experience and observation, is, I find, borne out not only by practitioners of long residence and experience in the Cape peninsula, but also by those resident in such places as Kimberley, Cradock, &c. These latter are unanimous in their view that during the summer months these higher altitudes in the colony are extremely trying to phthisical patients. The excessive heat, though the air be dry, seems to do more harm in the way of exhausting the phthisical patient than the dry air and sunshine do good. During the summer months in the Cape peninsula the rainfall is small, rarely exceeding six inches for the six months October to March, and the temperature is never excessive. The prevailing south-east wind is dry and cool, and in the suburbs of Cape Town, such as Wynberg, Newlands, or Sea Point, the boisterousness which the wind occasionally assumes can always be avoided. In an excellent article on this subject published in the *South African Medical Journal* of May, 1893, Dr. C. F. K. Murray, of Wynberg, says; "It is want of precise knowledge ..... that leads to the idea, 'Get away at once up country, and don't stop in the Cape peninsula.' I maintain that such is bad advice and must be qualified by careful consideration of the patient's actual condition, the season of the year, and the type of the case." My own experience has proved to me conclusively that cases of phthisis which are likely to be influenced by climate do extremely well in the Cape peninsula during the summer months, while I am equally certain that much harm is often done to such cases by hurrying them into the blazing plains of the Karoo and higher "plateaus," there to exhaust themselves in the unaccustomed heat. I have not in this short note sought to introduce statistics showing how equable is the climate of the Cape peninsula during the months of October to March, because such are easily available to all; but I feel, judging by my own experience and that of many of my *confrères*, that the logical deductions have not always been drawn from these figures. To conclude, then, I would recommend that early phthisical cases leaving England from October to March—and it is in these months that most do leave—should remain in and about the Cape peninsula, certainly not going beyond Ceres, until March. With May our winter rains set in, and it is then most advisable that all chest cases should seek a habitat beyond our winter rain-belt in the higher altitudes.

I am, Sirs, yours truly,

E. BARNARD FULLER, M.B., C.M., F.R.C.S. Edin.

Cape Town, Jan. 25th, 1897.

H. H.—Brown bread is made with bran, which contains a high proportion of mineral matters, but it is doubtful whether bran possesses any advantages from the dietetic point of view. It escapes digestive action and acts as a mechanical irritant in the intestinal tract. The special bread our correspondent mentions is free from irritating branny particles, but is considerably enriched by the addition of a notable proportion of wheat-germ, which is highly nitrogenous.

SOUTHALL'S NEW SANITARY TOWEL.

THE well-known sanitary towel for ladies' use, supplied by Messrs. Southall Brothers and Barclay of Birmingham, has from time to time undergone various improvements, and the same makers have now introduced a thoroughly serviceable modification at a much lower price for the benefit of those who do not care to obtain the superior qualities. The new towel consists essentially of an absorbent material made by a patented process from finely divided cellulose mixed with a soft white infusorial earth ("Dimatos") lighter than magnesia, and capable of absorbing upwards of six times its weight of liquids. This powder under the microscope is seen to consist of infusorial skeletons. It is free from starch and does not fuse on heating, as would be the case if borax were present. It is highly diffusive, as well as absorbent, and when enclosed in an envelope of absorbent wool wadding forms a pad peculiarly well adapted for the purpose for which it is intended. Cellulose by itself, when manufactured into wadding, loses its soft and elastic properties as soon as it is wetted, becoming, in fact, almost a pulp, but when it is combined with "dimatos" the compound possesses all the valuable diffusive properties of cellulose, together with the elasticity of absorbent cotton. The towels are about nine inches long and three inches wide, and have loops at each end for the purpose of fastening them in position. They are sold in packets of twelve for sixpence, so that the price of each towel is a halfpenny.

INTESTINAL IRRIGATION IN PUERPERAL ECLAMPSIA.

To the Editors of THE LANCET.

SIRS,—An apparatus for rectal irrigation similar to that described by Dr. R. C. Kemp in the *New York Medical Journal*, and referred to at page 1038 of THE LANCET for April 10th, was used by me about two and a half years ago in a case of puerperal eclampsia, pending completion of delivery. On this occasion I obtained very marked success with an improvised apparatus. I made a note of it at the time and had a nozzle constructed, but no further cases of eclampsia have occurred in my practice. The apparatus might have been used in a case of uræmic convulsions, complicated with glycosuria, which subsequently came under my care, but ordinary measures fortunately proved successful, and as long as the well-trodden paths of treatment lead to the desired end I prefer to keep to them, rather than to follow new lines.

I am, Sirs, yours faithfully,

G. G. GIDLEY, L.R.C.P. Lond., M.R.C.S. Eng.

Cullompton, Devonshire, April 11th, 1897.

A Constant Reader will probably get the information he requires by writing to the Laboratory Principal of the Royal Agricultural Society of England, 22, Tudor-street, New Bridge-street, London, E.C.

THE AFTER-CARE ASSOCIATION.

THIS excellent society has charged itself with the duty of looking after poor patients discharged recovered from asylums for the insane. It is the only one of its kind in the kingdom, and deserves every support. At the annual meeting held recently the chair was taken by the Archdeacon of London, and among those present were Dr. Henry Rayner and Dr. Nicolson. The report showed that 135 patients had been helped in various ways, and the accounts, we are glad to see, show a balance on the right side; but with a larger income much more work could be done, and we earnestly hope that the appeal of the committee for the coming year will meet with a generous response.

Common Sense.—The origin, though unknown, is not more mysterious than the origin of most other diseases, and the mode of transmission is well known. All the recognised text-books supply the answers to the questions.

B. R. D.—We think that B. should resign the case to A., unless his further attendance in consultation be desired.

A PHOTOGRAPHIC EXPOSURE.

IN the discussion which followed Mr. Campbell Swinton's interesting demonstration of improved x ray apparatus at the Camera Club on April 12th one of the speakers mentioned that he possessed a fluorescent screen measuring 6 ft. by 1½ ft. It is intended to show the bones and soft parts of a full-length figure all at one view, and on an occasion when the apparatus was being inspected by a number of persons it was the means of creating an embarrassment almost beyond the power of words to describe. A lady having incautiously passed in the line of the rays was suddenly displayed on the large screen, and as dress materials are very transparent to the rays her costume, of course, did not count for much in the picture!

Mr. R. Denison Pedley will obtain the information he requires by communicating directly with Professor E. Waymouth Reid, University College, Dundee.

ERRATUM.—The address of the importers of the Jyree tea, Messrs. A. C. Irwin and Co., is Billiter-buildings, Billiter-street, E.C., and not Great Tower-street, as stated in our issue of April 10th.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Somerset County Herald, Hereford Weekly Times, Sussex Daily News, Wigan Examiner, Lincoln Gazette, Suffolk Chronicle, South-Eastern Gazette, Citizen, Scotsman, Times of India, Wolverhampton Chronicle, Pioneer Mail, Devon Weekly Times, Leicester Daily Post, Portsmouth Times, Architect, Hampshire Post, Derby Mercury, Manchester Guardian, Kentish Mail, Liverpool Daily Post, Builder, Isle of Wight Times, Ripley Advertiser, Alcester Chronicle, Leeds Mercury, Woburn Reporter, Ilfracombe Gazette, Bradford Argus, Birmingham Gazette, Poole Times, Chatham News, Newbury Weekly News, East Anglian Times, Brighton Gazette, Bristol Mercury, Dundee Courier, Coleshill Chronicle, Kidderminster Sun, Western Mail, Cork Constitution, Hastings Times, Herne Bay Argus, City Press, Reading Mercury, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Mining Journal, Sanitary Record, Evening Citizen (Glasgow), Surrey Advertiser, Tenby and County News, Local Government Journal, Levant Herald, Cape Times, Brisbane Courier, Berkshire Chronicle, Singapore Free Press, Watford Observer, Watford and West Herts Post, Times of India (Bombay), Yorkshire Post, Express and Star, Wellingborough News, Yarmouth Mercury, Merthyr Times, Chesham Examiner, &c., &c.*

The Lumleian Lectures

ON

SOME PROBLEMS IN CONNEXION WITH APHASIA AND OTHER SPEECH DEFECTS.

Delivered before the Royal College of Physicians of London on April 1st, 6th, and 8th, 1897,

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,

CENSOR OF THE COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE III.[1]

Delivered on April 8th, 1897.

MR. PRESIDENT AND GENTLEMEN,—At the close of the last lecture I considered the different degrees of amnesia verbalis that may result from functional defects or partial lesions of the left auditory word-centre. We must now consider the effects produced by more serious lesions of this centre.

(*b*) *Effects produced by destruction of the left auditory word-centre.*—Where, instead of partial or mere functional defects, we have to do with more or less complete destruction of the left auditory word-centre by some organic disease a correspondingly complete word-deafness is produced, so that the patient is no longer able to comprehend spoken language. Spoken words become to such a patient mere meaningless sounds. As I have already pointed out, word-blindness (or alexia) is also an occasional consequence of such a lesion, though it is not to be regarded as a necessary accompaniment, whatever Wernicke and Déjerine may say to the contrary. These authorities, moreover, as well as Mirallié, hold that paraphasia is the kind of speech defect that is entailed by destruction of the auditory word-centre. Wyllie also, in his recent work on "The Disorders of Speech," says (p. 289) that the extreme defect in an "auditive" in consequence of this lesion would be what is termed "gibberish aphasia," and adds: "In general, the destruction of the auditory centre leaves the patient in possession of considerable powers of expression." This question as to the nature of the alteration of speech that goes with destruction of the auditory word-centre is a very interesting and important one, and will require careful consideration.

The views that I entertained on this subject some years ago were thus expressed[2]: "Suppose a person to be suffering from defective activity of the auditory word-centre, so that names cannot be recalled 'voluntarily' or by 'association.' There would already be great hesitation and difficulties in the expression of thoughts both in speech and in writing. But suppose this mere defective activity to be replaced by actual destruction of the left auditory word-centre so that its functional activity became actually lost, words could then, of course, neither be recalled 'voluntarily' nor by 'association,' and, still further, they could not be perceived and consequently could not be imitated. An individual thus affected would neither be able to speak nor to write—that is, he would be completely aphasic, with the superadded peculiarity that he would not readily comprehend spoken and perhaps written language." It should be observed that these statements were made partly as *a priori* deductions and partly as a result of the observation of actual cases, though at this period there had only been too few of them. Still, it seemed to me then—and from several points of view would still seem a legitimate conclusion—that loss of articulate speech should result from destruction of the auditory word-centre, just as agraphia results from destruction of the visual word-centre. Ballet[3] and Ross,[4] following me, expressed very similar views, though the majority of writers have rather followed Wernicke, and regarded paraphasia as the natural accompaniment of word-deafness.

[1] Lectures I. and II. were published in THE LANCET of April 3rd and April 10th, 1897, respectively.

[2] The Brain as an Organ of Mind, 1880, p. 685.

[3] Le Langage Intérieur, 1886, pp. 91 and 166.

[4] On Aphasia, 1887, p. 119.

Now that more cases have been observed we are in a better position for throwing light upon this point. An examination of the recorded observations in which the lesion has been limited to the hinder part of the first, and perhaps also of the second, left temporal convolutions (without perceptibly encroaching upon the visual word-centre) shows surprisingly different results in regard to the nature and degree of the speech alteration met with. In some of the cases there has been aphasia; in others a more or less marked paraphasia; whilst in two or three of the cases the defect in voluntary speech has been less marked. Thus, looking to the same sixteen cases of destruction of the auditory word-centre to which I previously referred[5] when speaking of the frequency with which word-blindness and agraphia occur as additional symptoms, I find that what is described as "motor aphasia" existed in six of them (viz., in Mirallié's list Nos. 7, 11, 12, and 25; and in Amidon's list Nos. 14 and 18). In six of the cases also some amount of paraphasia existed (viz., in Mirallié's list Nos. 3, 4, 19, 21, and 23; and in Amidon's list No. 7). In one case (Mirallié's No. 14) both aphasia and paraphasia are said to have existed; while in the three remaining cases (Amidon's Nos. 6, 15, and 17) voluntary speech seems to have been rather less affected.[6]

Thus it will be seen that we have all been more or less wrong; and I must confess that the revelation of these apparently contradictory results in the way of speech disturbance in association with word-deafness surprised me not a little. The meaning of such remarkable variations demands a careful consideration.

The three cases last referred to in which voluntary speech has been least interfered with are, I believe, altogether exceptional. One of them is a case recorded by Claus,[7] concerning which, unfortunately, there are only a few meagre details.

CASE 22.—A man, aged sixty-eight years, understood nothing said to him. He answered always wrongly, while he spoke correctly. His intelligence was weakened. His hearing was good. A focus of softening was found involving the left first temporal convolution, except its anterior third. This disorganised portion of the cortex and also the corresponding border of the second temporal convolution had a brown colour.

I have been unable to obtain any further particulars concerning this case, as the periodical in which it is reported is not contained in either of the libraries to which I have had access. It seems to be Case No. 20 in the "Table of Cases of Sensory Aphasia with Lesions and Symptoms" cited by Allen Starr,[8] and there also no further details are given. No weight, therefore, can be attached to this example, the details of which are so incomplete. The second case is one that was originally recorded by Wernicke,[9] and the following are all the essential details that are given.

CASE 23.—A woman, aged seventy-five years, was admitted to hospital on Oct. 7th, 1873, showing well-marked indications of old age. It was ascertained from her relatives that her speech had suddenly become troubled and almost lost on Nov. 2nd, 1872. On admission her psychical condition seemed to be that of a crazed person complicated with aphasia. She mostly lay huddled up in bed, and suffered from incontinence of urine and of fæces. She answered all questions put to her quite wrongly, and did not attempt to do anything she was told. She paid little attention to her surroundings and showed no desire to make any communications concerning her distressing condition. Her spontaneous speech was comparatively insignificant, though it was sufficient to show she was not suffering from motor aphasia. Her speech trouble was further shown by her alteration and displacement of words. Thus she often said correctly, "I thank you heartily," and another time, "I thank you most givelv," &c.; "I am quite ill"; "Ah! how cold I am"; "You are a kind gentleman." These were usual expressions; yet the medical man whom she had just called a kind gentleman she called soon after "mein Tochtel" or "mein Sohnel." An ophthalmoscopic examination on Nov. 5th, 1873, showed grey atrophy of the right optic disc. Sensibility seemed intact, and the hand-grip was weak, but equal on the two sides. More exact observations on these points were not made. There was no improvement in her psychical or bodily symptoms, and death occurred as a result of intestinal troubles on Dec. 1st, 1874. At the

[5] Excepting that I omit Mirallié's Case 10, and include instead his Case 2, where the only lesion beyond the destruction of the first temporal convolution was a very minute "plaque jaune," no more than a millimetre square, situated in the upper border of the foot of the third frontal convolution.

[6] Numbers of the cases of "sensory aphasia" hitherto recorded are comparatively valueless for the purpose of any critical study of their symptoms, either on account of the nature, extent, and complication of the lesions, or from the paucity of the clinical details, or perhaps from two or three of these causes in combination. Among such more or less vague cases I include thirteen in Mirallié's list (viz., Nos. 2, 15, 18, 20, 22, 27, 28, 32, 33, 34, 35, 36, and 37), and three in Amidon's list (viz., Nos. 8, 9, and 22). In four other cases—namely, Nos. 10, 11, and 17 of Mirallié's list, and No. 20 of Amidon's—there was a lesion in Broca's centre as well as in the auditory word-centre.

[7] Der Irrenfreund, No. 6, 1883.

[9] Der Aphasische Symptomen-Complex, 1874, p. 43.

Hosted by Google

necropsy there was found an increase in the sub-arachnoid fluid, and the convolutions generally of both hemispheres were somewhat wasted. There was also an excess of fluid in the lateral ventricles. All the brain arteries were highly atheromatous, and there was thrombosis of some of the terminal branches of the left middle cerebral artery. The whole of the upper temporal convolution and part of the supra-marginal lobule were in a state of yellow softening. The island of Reil was intact.

It will be seen from the above particulars that this patient's spontaneous speech was extremely limited and that she made frequent mistakes in words and in their pronunciation. The statement contained in Amidon's abstract, therefore, that her "spontaneous speech was very good," certainly goes far beyond what there is any warrant for. It is worthy of note also that the auditory word-centre may not have been entirely destroyed, since the second temporal convolution seems not to have been at all involved. In the previous case, reported by Claus, it should also be observed that the second temporal convolution was only very slightly involved. It is merely said that its upper border was affected ("had a brown colour").

The third case, curiously enough, has often been quoted as though it were a typical example of word-deafness rather than one of an unusual character. It was recorded by Giraudeau,[10] and some of the principal details are these.

CASE 24.—The patient, a woman, aged forty years, had previously enjoyed good health, though she had never menstruated. For three months before admission to l'Hôpital St. Antoine she had suffered from a constant headache, with nocturnal exacerbations of such a character as to render sleep impossible. There had been no vomiting or epileptiform attacks. For upwards of a month before admission she was obliged to give up work in consequence of the severity of the pain. At about the same time it was observed that she no longer understood what was said to her and that she did not answer when spoken to. This information was obtained from the persons who accompanied her to the hospital. On admission the patient was found to be very stout; there was no fever, the right pupil was slightly dilated, and there was severe headache. When asked her name she raised her head, but did not answer. When asked a second time she answered, "What do you say?" and on the same question being put a third time she said, "I don't understand." When asked a fourth time she answered correctly, "Marie Bouquinet." On being asked, "How long have you been ill?" she evinced the same difficulty of understanding, but replied, after a time, "Three months." When asked to give her address she replied, "Perhaps for three months and a half." Being interrogated as to her occupation, she presented the prescriptions of the physician who treated her in the town, and added, "A white powder" (sulphate of quinine). On several occasions we changed the mode of our interrogations, but the replies of the patient were always analogous to those mentioned above. After having by great difficulty made her understand a question by frequent repetition she answered; but whatever subsequent questions were put to her she followed her first idea, and her subsequent replies had no relation whatever to the questions put to her. Sometimes, however, it was impossible to make her understand our meaning at all, and to every question addressed to her she invariably replied: "What do you say? I don't understand. Cure me." Her hearing however, was unaffected; there was no discharge from the ear; she heard the ticking of a watch, and turned her head at any slight noise made near her. Vision was good in both eyes, and there was no word-blindness, for she could easily read the headings of the bed-ticket and written questions put to her, to which she replied verbally or in writing after a little reflection. Tactile sensibility was preserved, as well as the senses of taste and smell, and her motor power was unaffected. Without entering into further details, suffice it to say that the psychical affection rapidly increased, and on the ninth day after her admission the word-deafness was complete, and whenever she was addressed she invariably said, "I do not understand," and then began to weep. The next day she fell into a state of coma and died. At the necropsy a sarcomatous tumour of the size of a walnut was found occupying the posterior part of the first and second temporo-sphenoidal convolutions of the left hemisphere, the rest of the brain being healthy.

Here the details are fortunately more ample. Although this patient's speech was limited, there was clearly neither aphasia nor paraphasia, and this may, I think, be explained either by supposing that the lesion in the early days did not destroy the whole of the auditory word-centre—which is more than possible seeing that the lesion was a tumour and also that the word-deafness was not absolute; or else that the patient was a strong "visual"—a person, therefore, in whom the excitation of Broca's centre might have been brought about directly from the visual word-centre, both in spontaneous speech and in reply to written questions. And to the latter she is expressly said to have replied "verbally or in writing, after a little reflection." This possibility might, of course, be applicable also in explanation of the other two cases.

There is an interesting point worth noticing here in reference to cases of partial word-deafness, illustrating the increased power of recollection or comprehension when two or more bonds of association are simultaneously called into activity. Thus, in a case of incomplete word-deafness observed by Fränkel, when the patient was asked, "What is a fork?" he replied, "I don't know what you say." But when a fork was shown to him at the same time that its name was pronounced he not only recognised the fork, but comprehended its name and repeated it, the visual image of the object here helping to revive the auditory image of the word. At other times when this same patient was questioned, at first he did not understand, but he would struggle to articulate the words used and would thus, after various attempts, arrive at the meaning of the question. Another instance in which visual impressions were habitually called upon to aid a damaged auditory centre was long ago recorded by Abercrombie in his "Inquiry into the Intellectual Powers," where he says (seventh edition, 1837, p. 158): "The gentleman to whom it referred could not be made to understand the name of an object if it was spoken to him, but understood it perfectly when it was written. His mental faculties were so entire that he was engaged in most extensive agricultural concerns, and he managed them with perfect correctness by means of a remarkable contrivance. He kept before him in the room where he transacted business a list of the words which were most apt to occur in his intercourse with his workmen. When one of them wished to communicate with him on any subject he first heard what the workman had to say, but without understanding him further than to catch the words. He then turned to the words in his written list, and whenever they met his eye he understood them perfectly. These particulars I had from his son, a gentleman of high intelligence."

This slight digression may serve to illustrate one of the two suggestions I have made in explanation of the comparatively slight defects in speech presented by the three altogether exceptional cases of word deafness to which I have above referred. But, before pursuing our attempt to explain the differences presented by the other cases, it will be well first of all to see what the results have been in two other sets of cases involving destruction of the left auditory word-centre as one component of the existing lesions—that is to say, in the two next sets of cases already cited for consideration—viz., (2) the cases in which there have been combined lesions of the auditory word-centres in each hemisphere; and (3) the cases in which the auditory and the visual word-centres have been destroyed or severely damaged in both hemispheres.

(2) DEFECTS RESULTING FROM LESIONS OF THE AUDITORY WORD-CENTRE IN EACH HEMISPHERE.

Cases of double lesion in the upper temporal convolutions are extremely rare. Only four such cases are known to me, and concerning these clinical details in three are unfortunately extremely meagre, consisting of particulars obtained from friends or others, rather than from the examination by a skilled observer.

The first of these cases to which I will refer is one that has been recorded by Kähler and Pick,[11] though the details are very scanty and of the kind above mentioned.
